# Preface

The present volume is an outgrowth of a Conference on Mathematical Tables held at Cambridge, Mass., on September 15-16, 1954, under the auspices of the National Science Foundation and the Massachusetts Institute of Technology. The purpose of the meeting was to evaluate the need for mathematical tables in the light of the availability of large scale computing machines. It was the consensus of opinion that in spite of the increasing use of the new machines the basic need for tables would continue to exist.

Numerical tables of mathematical functions are in continual demand by scientists and engineers. A greater variety of functions and higher accuracy of tabulation are now required as a result of scientific advances and, especially, of the increasing use of automatic computers. In the latter connection, the tables serve mainly for preliminary surveys of problems before programming for machine operation. For those without easy access to machines, such tables are, of course, indispensable.

Consequently, the Conference recognized that there was a pressing need for a modernized version of the classical tables of functions of Jahnke-Emde. To implement the project, the National Science Foundation requested the National Bureau of Standards to prepare such a volume and established an Ad Hoc Advisory Committee, with Professor Philip M. Morse of the Massachusetts Institute of Technology as chairman, to advise the staff of the National Bureau of Standards during the course of its preparation. In addition to the Chairman, the Committee consisted of A. Erdelyi, M. C. Gray, N. Metropolis, J. B. Rosser, H. C. Thacher, Jr., John Todd, C. B. Tompkins, and J. W. Tukey.

The primary aim has been to include a maximum of useful information within the limits of a moderately large volume, with particular attention to the needs of scientists in all fields. An attempt has been made to cover the entire field of special functions. To carry out the goal set forth by the Ad Hoc Committee, it has been necessary to supplement the tables by including the mathematical properties that are important in computation work, as well as by providing numerical methods which demonstrate the use and extension of the tables.

The Handbook was prepared under the direction of the late Milton Abramowitz, and Irene A. Stegun. Its success has depended greatly upon the cooperation of many mathematicians. Their efforts together with the cooperation of the Ad Hoc Committee are greatly appreciated. The particular contributions of these and other individuals are acknowledged at appropriate places in the text. The sponsorship of the National Science Foundation for the preparation of the material is gratefully recognized.

It is hoped that this volume will not only meet the needs of all table users but will in many cases acquaint its users with new functions.

# Preface to the Ninth Printing

The enthusiastic reception accorded the "Handbook of Mathematical Functions" is little short of unprecedented in the long history of mathematical tables that began when John Napier published his tables of logarithms in 1614. Only four and one-half years after the first copy came from the press in 1964, Myron Tribus, the Assistant Secretary of Commerce for Science and Technology, presented the 100,000th copy of the Handbook to Lee A. DuBridge, then Science Advisor to the President. Today, total distribution is approaching the 150,000 mark at a scarcely diminished rate.

The success of the Handbook has not ended our interest in the subject. On the contrary, we continue our close watch over the growing and changing world of computation and to discuss with outside experts and among ourselves the various proposals for possible extension or supplementation of the formulas, methods and tables that make up the Handbook.

In keeping with previous policy, a number of errors discovered since the last printing have been corrected. Aside from this, the mathematical tables and accompanying text are unaltered. However, some noteworthy changes have been made in Chapter 2: Physical Constants and Conversion Factors, pp. 6-8. The table on page 7 has been revised to give the values of physical constants obtained in a recent reevaluation; and pages 6 and 8 have been modified to reflect changes in definition and nomenclature of physical units and in the values adopted for the acceleration due to gravity in the revised Potsdam system.

The record of continuing acceptance of the Handbook, the praise that has come from all quarters, and the fact that it is one of the most-quoted scientific publications in recent years are evidence that the hope expressed by Dr. Astin in his Preface is being amply fulfilled.

# Foreword

This volume is the result of the cooperative effort of many persons and a number of organizations. The National Bureau of Standards has long been turning out mathematical tables and has had under consideration, for at least 10 years, the production of a compendium like the present one. During a Conference on Tables, called by the NBS Applied Mathematics Division on May 15, 1952, Dr. Abramowitz of that Division mentioned preliminary plans for such an undertaking, but indicated the need for technical advice and financial support.

The Mathematics Division of the National Research Council has also had an active interest in tables; since 1943 it has published the quarterly journal, "Mathematical Tables and Aids to Computation" (MTAC), editorial supervision being exercised by a Committee of the Division.

Subsequent to the NBS Conference on Tables in 1952 the attention of the National Science Foundation was drawn to the desirability of financing activity in table production. With its support a 2-day Conference on Tables was called at the Massachusetts Institute of Technology on September 15–16, 1954, to discuss the needs for tables of various kinds. Twenty-eight persons attended, representing scientists and engineers using tables as well as table producers. This conference reached consensus on several conclusions and recommendations, which were set forth in the published Report of the Conference. There was general agreement, for example, "that the advent of high-speed computing equipment changed the task of table making but definitely did not remove the need for tables". It was also agreed that "an outstanding need is for a Handbook of Tables for the Occasional Computer, with tables of usually encountered functions and a set of formulas and tables for interpolation and other techniques useful to the occasional computer". The Report suggested that the NBS undertake the production of such a Handbook and that the NSF contribute financial assistance. The Conference elected, from its participants, the following Committee: P. M. Morse (Chairman), M. Abramowitz, J. H. Curtiss, R. W. Hamming, D. H. Lehmer, C. B. Tompkins, J. W. Tukey, to help implement these and other recommendations.

The Bureau of Standards undertook to produce the recommended tables and the National Science Foundation made funds available. To provide technical guidance to the Mathematics Division of the Bureau, which carried out the work, and to provide the NSF with independent judgments on grants for the work, the Conference Committee was reconstituted as the Committee on Revision of Mathematical Tables of the Mathematics Division of the National Research Council. This, after some changes of membership, became the Committee which is signing this Foreword. The present volume is evidence that Conferences can sometimes reach conclusions and that their recommendations sometimes get acted on.

Active work was started at the Bureau in 1956. The overall plan, the selection of authors for the various chapters, and the enthusiasm required to begin the task were contributions of Dr. Abramowitz. Since his untimely death, the effort has continued under the general direction of Irene A. Stegun. The workers at the Bureau and the members of the Committee have had many discussions about content, style and layout. Though many details have had to be argued out as they came up, the basic specifications of the volume have remained the same as were outlined by the Massachusetts Institute of Technology Conference of 1954.

The Committee wishes here to register its commendation of the magnitude and quality of the task carried out by the staff of the NBS Computing Section and their expert collaborators in planning, collecting and editing these Tables, and its appreciation of the willingness with which its various suggestions were incorporated into the plans. We hope this resulting volume will be judged by its users to be a worthy memorial to the vision and industry of its chief architect, Milton Abramowitz. We regret he did not live to see its publication.

# Handbook of Mathematical Functions

# Formulas, Graphs, and Mathematical Tables

Edited by Milton Abramowitz and Irene A. Stegun

## 1. Introduction

The present Handbook has been designed to provide scientific investigators with a comprehensive and self-contained summary of the mathematical functions that arise in physical and engineering problems. The well-known Tables of Functions by E. Jahnke and F. Emde has been invaluable to workers in these fields in its many editions[1] during the past half-century. The present volume extends the work of these authors by giving more extensive and more accurate numerical tables, and by giving larger collections of mathematical properties of the tabulated functions. The number of functions covered has also been increased.

The classification of functions and organization of the chapters in this Handbook is similar to that of An Index of Mathematical Tables by A. Fletcher, J. C. P. Miller, and L. Rosenhead.[2] In general, the chapters contain numerical tables, graphs, polynomial or rational approximations for automatic computers, and statements of the principal mathematical properties of the tabulated functions, particularly those of computational importance. Many numerical examples are given to illustrate the use of the tables and also the computation of function values which lie outside their range. At the end of the text in each chapter there is a short bibliography giving books and papers in which proofs of the mathematical properties stated in the chapter may be found. Also listed in the bibliographies are the more important numerical tables. Comprehensive lists of tables are given in the Index mentioned above, and current information on new tables is to be found in the National Research Council quarterly Mathematics of Computation (formerly Mathematical Tables and Other Aids to Computation).

The mathematical notations used in this Handbook are those commonly adopted in standard texts, particularly Higher Transcendental Functions, Volumes 1–3, by A. Erdélyi, W. Magnus, F. Oberhettinger and F. G. Tricomi (McGraw-Hill, 1953–55). Some alternative notations have also been listed. The introduction of new symbols has been kept to a minimum, and an effort has been made to avoid the use of conflicting notation.

## 2. Accuracy of the Tables

The number of significant figures given in each table has depended to some extent on the number available in existing tabulations. There has been no attempt to make it uniform throughout the Handbook, which would have been a costly and laborious undertaking. In most tables at least five significant figures have been provided, and the tabular intervals have generally been chosen to ensure that linear interpolation will yield four- or five-figure accuracy, which suffices in most physical applications. Users requiring higher precision in their interpolates may obtain them by use of higher-order interpolation procedures, described below.

In certain tables many-figured function values are given at irregular intervals in the argument. An example is provided by Table 9.4. The purpose of these tables is to furnish "key values" for the checking of programs for automatic computers; no question of interpolation arises.

The maximum end-figure error, or "tolerance" in the tables in this Handbook is $6/10$ of 1 unit everywhere in the case of the elementary functions, and 1 unit in the case of the higher functions except in a few cases where it has been permitted to rise to 2 units.

## 3. Auxiliary Functions and Arguments

One of the objects of this Handbook is to provide tables or computing methods which enable the user to evaluate the tabulated functions over complete ranges of real values of their parameters. In order to achieve this object, frequent use has been made of auxiliary functions to remove the infinite part of the original functions at their singularities, and auxiliary arguments to cope with infinite ranges. An example will make the procedure clear.

The exponential integral of positive argument is given by

$$\begin{aligned}\mathrm{Ei}(x)&=\int_{-\infty}^{x}\frac{e^u}{u}du\\&=\gamma+\ln x+\frac{x}{1\cdot 1!}+\frac{x^2}{2\cdot 2!}+\frac{x^3}{3\cdot 3!}+\dots\\&\sim\frac{e^x}{x}\left[1+\frac{1!}{x}+\frac{2!}{x^2}+\frac{3!}{x^3}+\dots\right](x\rightarrow\infty)\end{aligned}$$

The logarithmic singularity precludes direct interpolation near $x=0$. The functions $\mathrm{Ei}(x)-\ln x$ and $x^{-1}[\mathrm{Ei}(x)-\ln x-\gamma]$, however, are well-behaved and readily interpolable in this region. Either will do as an auxiliary function; the latter was in fact selected as it yields slightly higher accuracy when $\mathrm{Ei}(x)$ is recovered. The function $x^{-1}[\mathrm{Ei}(x)-\ln x-\gamma]$ has been tabulated to nine decimals for the range $0\leq x\leq\frac{1}{2}$. For $\frac{1}{2}\leq x\leq 2$, $\mathrm{Ei}(x)$ is sufficiently well-behaved to admit direct tabulation, but for larger values of $x$, its exponential character predominates. A smoother and more readily interpolable function for large $x$ is $xe^{-x}\mathrm{Ei}(x)$; this has been tabulated for $2\leq x\leq 10$. Finally, the range $10\leq x\leq\infty$ is covered by use of the inverse argument $x^{-1}$. Twenty-one entries of $xe^{-x}\mathrm{Ei}(x)$, corresponding to $x^{-1}=.1(-.005)0$, suffice to produce an interpolable table.

## 4. Interpolation

The tables in this Handbook are not provided with differences or other aids to interpolation, because it was felt that the space they require could be better employed by the tabulation of additional functions. Admittedly aids could have been given without consuming extra space by increasing the intervals of tabulation, but this would have conflicted with the requirement that linear interpolation is accurate to four or five figures.

For applications in which linear interpolation is insufficiently accurate it is intended that Lagrange's formula or Aitken's method of iterative linear interpolation[3] be used. To help the user, there is a statement at the foot of most tables of the maximum error in a linear interpolate, and the number of function values needed in Lagrange's formula or Aitken's method to interpolate to full tabular accuracy.

As an example, consider the following extract from Table 5.1.

| $x$ | $xe^xE_1(x)$ | $x$ | $xe^xE_1(x)$ |
|---|---|---|---|
| 7.5 | .89268 7854 | 8.0 | .89823 7113 |
| 7.6 | .89384 6312 | 8.1 | .89927 7888 |
| 7.7 | .89497 9666 | 8.2 | .90029 7306 |
| 7.8 | .89608 8737 | 8.3 | .90129 6033 |
| 7.9 | .89717 4302 | 8.4 | .90227 4695 |

$$\begin{bmatrix}(-6)3\\ \ \ \ 5\end{bmatrix}$$

The numbers in the square brackets mean that the maximum error in a linear interpolate is $3\times 10^{-6}$, and that to interpolate to the full tabular accuracy five points must be used in Lagrange's and Aitken's methods.

Let us suppose that we wish to compute the value of $xe^xE_1(x)$ for $x=7.9527$ from this table. We describe in turn the application of the methods of linear interpolation, Lagrange and Aitken, and of alternative methods based on differences and Taylor's series.

(1) Linear interpolation. The formula for this process is given by

$$f_p=(1-p)f_0+pf_1$$

where $f_0$, $f_1$ are consecutive tabular values of the function, corresponding to arguments $x_0$, $x_1$, respectively; $p$ is the given fraction of the argument interval

$$p=(x-x_0)/(x_1-x_0)$$

and $f_p$ the required interpolate. In the present instance, we have

$$f_0=.89717\ 4302 \qquad f_1=.89823\ 7113 \qquad p=.527$$

The most convenient way to evaluate the formula on a desk calculating machine is to set $f_0$ and $f_1$ in turn on the keyboard, and carry out the multiplications by $1-p$ and $p$ cumulatively; a partial check is then provided by the multiplier dial reading unity. We obtain

$$\begin{aligned}f_{.527}&=(1-.527)(.89717\ 4302)+.527(.89823\ 7113)\\&=.89773\ 4403.\end{aligned}$$

Since it is known that there is a possible error of $3\times 10^{-6}$ in the linear formula, we round off this result to .89773. The maximum possible error in this answer is composed of the error committed by the last rounding, that is, $.4403\times10^{-5}$, plus $3\times10^{-6}$, and so certainly cannot exceed $.8\times10^{-5}$.

---

[3] A. C. Aitken, On interpolation by iteration of proportional parts, without the use of differences, Proc. Edinburgh Math. Soc. 3, 56–76 (1932).

(2) Lagrange's formula. In this example, the relevant formula is the 5-point one, given by

$$f=A_{-2}(p)f_{-2}+A_{-1}(p)f_{-1}+A_0(p)f_0+A_1(p)f_1+A_2(p)f_2$$

Tables of the coefficients $A_k(p)$ are given in chapter 25 for the range $p=0(.01)1$. We evaluate the formula for $p=.52$, .53 and .54 in turn. Again, in each evaluation we accumulate the $A_k(p)$ in the multiplier register since their sum is unity. We now have the following subtable.

| $x$ | $xe^xE_1(x)$ | | |
|---|---|---|---|
| 7.952 | .89772 9757 | | |
| | | 10622 | |
| 7.953 | .89774 0379 | | −2 |
| | | 10620 | |
| 7.954 | .89775 0999 | | |

The numbers in the third and fourth columns are the first and second differences of the values of $xe^xE_1(x)$ (see below); the smallness of the second difference provides a check on the three interpolations. The required value is now obtained by linear interpolation:

$$f_p=.3(.89772\ 9757)+.7(.89774\ 0379)$$
$$=.89773\ 7192.$$

In cases where the correct order of the Lagrange polynomial is not known, one of the preliminary interpolations may have to be performed with polynomials of two or more different orders as a check on their adequacy.

(3) Aitken's method of iterative linear interpolation. The scheme for carrying out this process in the present example is as follows:

| $n$ | $x_n$ | $y_n=xe^xE_1(x)$ | $y_{0,n}$ | $y_{0,1,n}$ | $y_{0,1,2,n}$ | $y_{0,1,2,3,n}$ | $x_n-x$ |
|---|---|---|---|---|---|---|---|
| 0 | 8.0 | .89823 7113 | | | | | .0473 |
| 1 | 7.9 | .89717 4302 | .89773 44034 | | | | −.0527 |
| 2 | 8.1 | .89927 7888 | .89774 48264 | .89773 71499 | | | .1473 |
| 3 | 7.8 | .89608 8737 | 2 90220 | 2394 | .89773 71938 | | −.1527 |
| 4 | 8.2 | .90029 7306 | 4 98773 | 1216 | 16 | 89773 71930 | .2473 |
| 5 | 7.7 | .89497 9666 | 2 35221 | 2706 | 43 | 30 | −.2527 |

Here

$$y_{0,n}=\frac{1}{x_n-x_0}\begin{vmatrix}y_0 & x_0-x\\ y_n & x_n-x\end{vmatrix}$$

$$y_{0,1,n}=\frac{1}{x_n-x_1}\begin{vmatrix}y_{0,1} & x_1-x\\ y_{0,n} & x_n-x\end{vmatrix}$$

$$y_{0,1,\ldots,m-1,m,n}=\frac{1}{x_n-x_m}\begin{vmatrix}y_{0,1,\ldots,m-1,m} & x_m-x\\ y_{0,1,\ldots,m-1,n} & x_n-x\end{vmatrix}$$

If the quantities $x_n-x$ and $x_m-x$ are used as multipliers when forming the cross-product on a desk machine, their accumulation $(x_n-x)-(x_m-x)$ in the multiplier register is the divisor to be used at that stage. An extra decimal place is usually carried in the intermediate interpolates to safeguard against accumulation of rounding errors.

The order in which the tabular values are used is immaterial to some extent, but to achieve the maximum rate of convergence and at the same time minimize accumulation of rounding errors, we begin, as in this example, with the tabular argument nearest to the given argument, then take the nearest of the remaining tabular arguments, and so on.

The number of tabular values required to achieve a given precision emerges naturally in the course of the iterations. Thus in the present example six values were used, even though it was known in advance that five would suffice. The extra row confirms the convergence and provides a valuable check.

(4) Difference formulas. We use the central difference notation (chapter 25),

$$\begin{array}{cccccc}
x_0 & f_0 & & & & \\
 & & \delta f_{1/2} & & & \\
x_1 & f_1 & & \delta^2 f_1 & & \\
 & & \delta f_{3/2} & & \delta^3 f_{3/2} & \\
x_2 & f_2 & & \delta^2 f_2 & & \delta^4 f_2\\
 & & \delta f_{5/2} & & \delta^3 f_{5/2} & \\
x_3 & f_3 & & \delta^2 f_3 & & \\
 & & \delta f_{7/2} & & & \\
x_4 & f_4 & & & &
\end{array}$$

Here

$$\delta f_{1/2}=f_1-f_0,\ \delta f_{3/2}=f_2-f_1,\ \ldots,$$
$$\delta^2 f_1=\delta f_{3/2}-\delta f_{1/2}=f_2-2f_1+f_0$$
$$\delta^3 f_{3/2}=\delta^2 f_2-\delta^2 f_1=f_3-3f_2+3f_1-f_0$$
$$\delta^4 f_2=\delta^3 f_{5/2}-\delta^3 f_{3/2}=f_4-4f_3+6f_2-4f_1+f_0$$

and so on.

In the present example the relevant part of the difference table is as follows, the differences being written in units of the last decimal place of the function, as is customary. The smallness of the high differences provides a check on the function values

| $x$ | $xe^xE_1(x)$ | $\delta^2 f$ | $\delta^4 f$ |
|---|---|---|---|
| 7.9 | .89717 4302 | −2 2754 | −34 |
| 8.0 | .89823 7113 | −2 2036 | −39 |

Applying, for example, Everett's interpolation formula

$$f_p=(1-p)f_0+E_2(p)\delta^2 f_0+E_4(p)\delta^4 f_0+\ \ldots$$
$$+pf_1+F_2(p)\delta^2 f_1+F_4(p)\delta^4 f_1+\ \ldots$$

and taking the numerical values of the interpolation coefficients $E_2(p)$, $E_4(p)$, $F_2(p)$ and $F_4(p)$ from Table 25.1, we find that

$$10^9 f_{.527} = .473(89717\ 4302) + .061196(2\ 2754) - .012(34)$$
$$+ .527(89823\ 7113) + .063439(2\ 2036) - .012(39)$$
$$= 89773\ 7193.$$

We may notice in passing that Everett's formula shows that the error in a linear interpolate is approximately

$$E_2(p)\delta^2 f_0 + F_2(p)\delta^2 f_1 \approx \tfrac{1}{2}[E_2(p) + F_2(p)][\delta^2 f_0 + \delta^2 f_1]$$

Since the maximum value of $|E_2(p)+F_2(p)|$ in the range $0<p<1$ is $\frac{1}{8}$, the maximum error in a linear interpolate is approximately

$$\frac{1}{16}|\delta^2 f_0 + \delta^2 f_1|, \text{ that is, } \frac{1}{16}|f_2 - f_1 - f_0 + f_{-1}|.$$

(5) Taylor's series. In cases where the successive derivatives of the tabulated function can be computed fairly easily, Taylor's expansion

$$f(x) = f(x_0) + (x-x_0)\frac{f'(x_0)}{1!} + (x-x_0)^2\frac{f''(x_0)}{2!}$$
$$+ (x-x_0)^3\frac{f'''(x_0)}{3!} + \ . \ . \ .$$

can be used. We first compute as many of the derivatives $f^{(n)}(x_0)$ as are significant, and then evaluate the series for the given value of $x$. An advisable check on the computed values of the derivatives is to reproduce the adjacent tabular values by evaluating the series for $x=x_{-1}$ and $x_1$.

In the present example, we have

$$f(x) = xe^x E_1(x)$$
$$f'(x) = (1+x^{-1})f(x) - 1$$
$$f''(x) = (1+x^{-1})f'(x) - x^{-2}f(x)$$
$$f'''(x) = (1+x^{-1})f''(x) - 2x^{-2}f'(x) + 2x^{-3}f(x).$$

With $x_0=7.9$ and $x-x_0=.0527$ our computations are as follows; an extra decimal has been retained in the values of the terms in the series to safeguard against accumulation of rounding errors.

| $k$ | $f^{(k)}(x_0)/k!$ | $(x-x_0)^k f^{(k)}(x_0)/k!$ |

## 5. Inverse Interpolation

With linear interpolation there is no difference in principle between direct and inverse interpolation. In cases where the linear formula provides an insufficiently accurate answer, two methods are available. We may interpolate directly, for example, by Lagrange's formula to prepare a new table at a fine interval in the neighborhood of the approximate value, and then apply accurate inverse linear interpolation to the subtabulated values. Alternatively, we may use Aitken's method or even possibly the Taylor's series method, with the roles of function and argument interchanged.

It is important to realize that the accuracy of an inverse interpolate may be very different from that of a direct interpolate. This is particularly true in regions where the function is slowly varying, for example, near a maximum or minimum. The maximum precision attainable in an inverse interpolate can be estimated with the aid of the formula

$$\Delta x \approx \Delta f / \frac{df}{dx}$$

in which $\Delta f$ is the maximum possible error in the function values.

Example. Given $xe^x E_1(x) = .9$, find $x$ from the table on page X.

(i) Inverse linear interpolation. The formula for $p$ is

$$p = (f_p - f_0)/(f_1 - f_0).$$

In the present example, we have

$$p = \frac{.9 - .89927\ 7888}{.90029\ 7306 - .89927\ 7888} = \frac{72\ 2112}{101\ 9418} = .708357.$$

The desired $x$ is therefore

$$x = x_0 + p(x_1 - x_0) = 8.1 + .708357(.1) = 8.17083\ 57$$

To estimate the possible error in this answer, we recall that the maximum error of direct linear interpolation in this table is $\Delta f = 3\times 10^{-6}$. An approximate value for $df/dx$ is the ratio of the first difference to the argument interval (chapter 25), in this case .010. Hence the maximum error in $x$ is approximately $3\times 10^{-6}/(.010)$, that is, .0003.

(ii) Subtabulation method. To improve the approximate value of $x$ just obtained, we interpolate directly for $p=.70$, .71 and .72 with the aid of Lagrange's 5-point formula,

| $x$ | $xe^x E_1(x)$ | $\delta$ | $\delta^2$ |
|---|---|---|---|
| 8. 170 | . 89999 3683 | | |
| | | 1 0151 | |
| 8. 171 | . 90000 3834 | | −2 |
| | | 1 0149 | |
| 8. 172 | . 90001 3983 | | |

Inverse linear interpolation in the new table gives

$$p = \frac{.9 - .89999\ 3683}{.00001\ 0151} = .6223$$

Hence $x = 8.17062\ 23$.

An estimate of the maximum error in this result is

$$\Delta f / \frac{df}{dx} \approx \frac{1\times 10^{-9}}{.010} = 1\times 10^{-7}$$

(iii) Aitken's method. This is carried out in the same manner as in direct interpolation.

| $n$ | $y_n = xe^x E_1(x)$ | $x_n$ | $x_{0,n}$ | $x_{0,1,n}$ | $x_{0,1,2,n}$ | $x_{0,1,2,3,n}$ | $y_n - y$ |
|---|---|---|---|---|---|---|---|
| 0 | .90029 7306 | 8.2 | | | | | .00029 7306 |
| 1 | .89927 7888 | 8.1 | 8.17083 5712 | | | | −.00072 2112 |
| 2 | .90129 6033 | 8.3 | 8.17023 1505 | 8.17061 9521 | | | .00129 6033 |
| 3 | .89823 7113 | 8.0 | 8.17113 8043 | 2 5948 | 8.17062 2244 | | −.00176 2887 |
| 4 | .90227 4695 | 8.4 | 8.16992 9437 | 1 7335 | 415 | 8.17062 2318 | .00227 4695 |
| 5 | .89717 4302 | 7.9 | 8.17144 0382 | 2 8142 | 231 | 265 | −.00282 5698 |

The estimate of the maximum error in this result is the same as in the subtabulation method. An indication of the error is also provided by the discrepancy in the highest interpolates, in this case $x_{0,1,2,3,4}$, and $x_{0,1,2,3,5}$.

## 6. Bivariate Interpolation

Bivariate interpolation is generally most simply performed as a sequence of univariate interpolations. We carry out the interpolation in one direction, by one of the methods already described, for several tabular values of the second argument in the neighborhood of its given value. The interpolates are differenced as a check, and interpolation is then carried out in the second direction.

An alternative procedure in the case of functions of a complex variable is to use the Taylor's series expansion, provided that successive derivatives of the function can be computed without much difficulty.

## 7. Generation of Functions from Recurrence Relations

Many of the special mathematical functions which depend on a parameter, called their index, order or degree, satisfy a linear difference equation (or recurrence relation) with respect to this parameter. Examples are furnished by the Legendre function $P_n(x)$, the Bessel function $J_n(x)$ and the exponential integral $E_n(x)$, for which we have the respective recurrence relations

$$(n+1)P_{n+1} - (2n+1)xP_n + nP_{n-1} = 0$$

$$J_{n+1} - \frac{2n}{x} J_n + J_{n-1} = 0$$

$$nE_{n+1} + xE_n = e^{-x}.$$

Particularly for automatic work, recurrence relations provide an important and powerful computing tool. If the values of $P_n(x)$ or $J_n(x)$ are known for two consecutive values of $n$, or $E_n(x)$ is known for one value of $n$, then the function may be computed for other values of $n$ by successive applications of the relation. Since generation is carried out perforce with rounded values, it is vital to know how errors may be propagated in the recurrence process. If the errors do not grow relative to the size of the wanted function, the process is said to be stable. If, however, the relative errors grow and will eventually overwhelm the wanted function, the process is unstable.

It is important to realize that stability may depend on (i) the particular solution of the difference equation being computed; (ii) the values of $x$ or other parameters in the difference equation; (iii) the direction in which the recurrence is being applied. Examples are as follows.

Stability—increasing $n$

$P_n(x)$, $P_n^m(x)$

$Q_n(x)$, $Q_n^m(x)$ $(x<1)$

$Y_n(x)$, $K_n(x)$

$J_{-n-\frac{1}{2}}(x)$, $I_{-n-\frac{1}{2}}(x)$

$E_n(x)$ $(n<x)$

Stability—decreasing $n$

$P_n(x)$, $P_n^m(x)$ $(x<1)$

$Q_n(x)$, $Q_n^m(x)$

$J_n(x)$, $I_n(x)$

$J_{n+\frac{1}{2}}(x)$, $I_{n+\frac{1}{2}}(x)$

$E_n(x)$ $(n>x)$

$F_n(\eta, \rho)$ (Coulomb wave function)

Illustrations of the generation of functions from their recurrence relations are given in the pertinent chapters. It is also shown that even in cases where the recurrence process is unstable, it may still be used when the starting values are known to sufficient accuracy.

Mention must also be made here of a refinement, due to J. C. P. Miller, which enables a recurrence process which is stable for decreasing $n$ to be applied without any knowledge of starting values for large $n$. Miller's algorithm, which is well-suited to automatic work, is described in **19.28, Example 1.**

## 2. Physical Constants and Conversion Factors

The tables in this chapter supply some of the more commonly needed physical constants and conversion factors.*

The International System of Units (SI) established in 1960 by the General Conference of Weights and Measures under the Treaty of the Meter is based upon: the meter (m) for length, defined as 1 650 763.73 wave-lengths in vacuum corresponding to the transition *$2p_{10}-5d_5$ of krypton 86; the kilogram (kg) for mass, defined as the mass of the prototype kilogram at Sevres, France; the second (s) for time, defined as the duration of 9 192 631 770 periods of the radiation corresponding to the transition between the two hyperfine levels of cesium 133; the kelvin (K) for temperature, defined as 1/273.16 of the thermodynamic temperature of the triple point of water; the ampere (A) for electric current, defined as the current which, if flowing in two infinitely long parallel wires *in vacuo* separated by one meter, would produce a force of $2 \times 10^{-7}$ newtons per meter of length between the wires; and the candela (cd) for luminous intensity, defined as the luminous intensity of 1/600 000 square meter of a perfect radiator at the temperature of freezing platinum.

All other units of SI are derived from these base units by assigning the value unity to the proportionality constants in the defining equations (official symbols for other SI units appear in Tables 2.1 and 2.2). Taking 1/100 of the meter as the unit for length and 1/1000 of the kilogram as the unit for mass gives rise similarly to the cgs system, often used in physics and chemistry.

SI, as it is ordinarily used in electromagnetism, is a rationalized system, i.e., the electromagnetic units of SI relate to the quantities appearing in the so-called rationalized electromagnetic equations. Thus, the force per unit length between two current-carrying parallel wires of infinite length separated by unit distance *in vacuo* is $2f = \mu_0 i_1 i_2 / 4\pi$, where $\mu_0$ has the value $4\pi \times 10^{-7}$H/m. The force between two electric charges *in vacuo* is correspondingly given by $f = q_1 q_2 / 4\pi\epsilon_0 r^2$, $\epsilon_0$ having the value $1/\mu_0 c^2$, where c is the speed of light in meters per second. ($\epsilon_0 \sim 8.854 \times 10^{-12}$F/m)

Setting $\mu_0$ equal to unity and deleting $4\pi$ from the denominator in the first equation above defines the cgs-emu system. Setting $\epsilon_0$ equal to unity and deleting $4\pi$ from the denominator in the second equation correspondingly defines the cgs-esu system. The cgs-emu and the cgs-esu systems are most frequently used in the unrationalized forms.

The values of constants given in Table 2.3 are based on an adjustment by Taylor, Parker, and Langenberg, Rev. Mod. Phys. 41, p.375 (1969). They are being considered for adoption by the Task Group on Fundamental Constants of the Committee on Data for Science and Technology, International Council of Scientific Unions. The uncertainties given are standard errors estimated from the experimental data included in the adjustment. Where applicable, values are based on the unified scale of atomic masses in which the atomic mass unit (u) is defined as 1/12 of the mass of the atom of the $^{12}C$ nuclide.

### Indeterminate Forms (L'Hospital's Rule)

**3.4.1** Let $f(x)$ and $g(x)$ be differentiable on an interval $a\leq x<b$ for which $g'(x)\neq 0$.

If

$$\lim_{x\to b-}f(x)=0\text{ and }\lim_{x\to b-}g(x)=0$$

or if

$$\lim_{x\to b-}f(x)=\infty\text{ and }\lim_{x\to b-}g(x)=\infty$$

and if

$$\lim_{x\to b-}\frac{f'(x)}{g'(x)}=l\text{ then }\lim_{x\to b-}\frac{f(x)}{g(x)}=l.$$

Both $b$ and $l$ may be finite or infinite.

### Maxima and Minima

**3.4.2** (1) *Functions of One Variable*

The function $y=f(x)$ has a maximum at $x=x_0$ if $f'(x_0)=0$ and $f''(x_0)<0$, and a minimum at $x=x_0$ if $f'(x_0)=0$ and $f''(x_0)>0$. Points $x_0$ for which $f'(x_0)=0$ are called stationary points.

**3.4.3** (2) *Functions of Two Variables*

The function $f(x, y)$ has a maximum or minimum for those values of $(x_0, y_0)$ for which

$$\frac{\partial f}{\partial x}=0, \quad \frac{\partial f}{\partial y}=0,$$

and for which $\begin{vmatrix} \partial^2 f/\partial x\partial y & \partial^2 f/\partial x^2 \\ \partial^2 f/\partial y^2 & \partial^2 f/\partial x\partial y \end{vmatrix}<0$;

(a) $f(x,y)$ has a maximum

$$\text{if } \frac{\partial^2 f}{\partial x^2}<0 \text{ and } \frac{\partial^2 f}{\partial y^2}<0 \text{ at } (x_0, y_0),$$

(b) $f(x,y)$ has a minimum

$$\text{if } \frac{\partial^2 f}{\partial x^2}>0 \text{ and } \frac{\partial^2 f}{\partial y^2}>0 \text{ at } (x_0, y_0).$$

## 3.5. Absolute and Relative Errors

(1) If $x_0$ is an approximation to the true value of $x$, then

**3.5.1** (a) the *absolute error* of $x_0$ is $\Delta x=x_0-x$, $x-x_0$ is the correction to $x$.

**3.5.2** (b) the *relative error* of $x_0$ is $\delta x=\frac{\Delta x}{x}\approx\frac{\Delta x}{x_0}$

**3.5.3** (c) the *percentage error* is 100 times the relative error.

**3.5.4** (2) The absolute error of the sum or difference of several numbers is at most equal to the sum of the absolute errors of the individual numbers.

**3.5.5** (3) If $f(x_1, x_2, \ldots, x_n)$ is a function of $x_1, x_2, \ldots, x_n$ and the absolute error in $x_i$ $(i=1, 2, \ldots n)$ is $\Delta x_i$, then the absolute error in $f$ is

$$\Delta f\approx\frac{\partial f}{\partial x_1}\,\Delta x_1+\frac{\partial f}{\partial x_2}\,\Delta x_2+\ldots+\frac{\partial f}{\partial x_n}\,\Delta x_n$$

**3.5.6** (4) The relative error of the product or quotient of several factors is at most equal to the sum of the relative errors of the individual factors.

**3.5.7**

(5) If $y=f(x)$, the relative error $\delta y=\frac{\Delta y}{y}\approx\frac{f'(x)}{f(x)}\,\Delta x$

### Approximate Values

If $|\epsilon|<<1, |\eta|<<1, b<<a,$

**3.5.8** $$(a+b)^k\approx a^k+ka^{k-1}b$$

**3.5.9** $$(1+\epsilon)(1+\eta)\approx 1+\epsilon+\eta$$

#### Polar Coordinates

## 3.8. Algebraic Equations

### Solution of Quadratic Equations

**3.8.1** Given $az^2+bz+c=0$,

$$z_{1,2}=-\left(\frac{b}{2a}\right)\pm\frac{1}{2a}q^{\frac12},\ q=b^2-4ac,$$

$$z_1+z_2=-b/a,\ z_1z_2=c/a$$

If $q>0$, two real roots,
$q=0$, two equal roots,
$q<0$, pair of complex conjugate roots.

### Solution of Cubic Equations

**3.8.2** Given $z^3+a_2z^2+a_1z+a_0=0$, let

$$q=\frac13 a_1-\frac19 a_2^2;\ r=\frac16(a_1a_2-3a_0)-\frac{1}{27}a_2^3.$$

If $q^3+r^2>0$, one real root and a pair of complex conjugate roots,

$q^3+r^2=0$, all roots real and at least two are equal,

$q^3+r^2<0$, all roots real (irreducible case).

Let

$$s_1=[r+(q^3+r^2)^{\frac12}]^{\frac13},\ s_2=[r-(q^3+r^2)^{\frac12}]^{\frac13}$$

then

$$z_1=(s_1+s_2)-\frac{a_2}{3}$$

$$z_2=-\frac12(s_1+s_2)-\frac{a_2}{3}+\frac{i\sqrt{3}}{2}(s_1-s_2)$$

$$z_3=-\frac12(s_1+s_2)-\frac{a_2}{3}-\frac{i\sqrt{3}}{2}(s_1-s_2).$$

If $z_1$, $z_2$, $z_3$ are the roots of the cubic equation

$$z_1+z_2+z_3=-a_2$$

$$z_1z_2+z_1z_3+z_2z_3=a_1$$

$$z_1z_2z_3=-a_0$$

### Solution of Quartic Equations

**3.8.3** Given $z^4+a_3z^3+a_2z^2+a_1z+a_0=0$, find the real root $u_1$ of the cubic equation

$$u^3-a_2u^2+(a_1a_3-4a_0)u-(a_1^2+a_0a_3^2-4a_0a_2)=0$$

and determine the four roots of the quartic as solutions of the two quadratic equations

$$v^2+\left[\frac{a_3}{2}\mp\left(\frac{a_3^2}{4}+u_1-a_2\right)^{\frac12}\right]v+\frac{u_1}{2}\mp\left[\left(\frac{u_1}{2}\right)^2-a_0\right]^{\frac12}=0$$

If all roots of the cubic equation are real, use the value of $u_1$ which gives real coefficients in the [*]quadratic equation and select signs so that if

$$z^4+a_3z^3+a_2z^2+a_1z+a_0=(z^2+p_1z+q_1)(z^2+p_2z+q_2),$$

then

$$p_1+p_2=a_3, p_1p_2+q_1+q_2=a_2, p_1q_2+p_2q_1=a_1, q_1q_2=a_0.$$

If $z_1$, $z_2$, $z_3$, $z_4$ are the roots,

$$\Sigma z_i=-a_3, \Sigma z_iz_jz_k=-a_1,$$

$$\Sigma z_iz_j=a_2, z_1z_2z_3z_4=a_0.$$

## 3.9. Successive Approximation Methods

### General Comments

**3.9.1** Let $x=x_1$ be an approximation to $x=\xi$ where $f(\xi)=0$ and both $x_1$ and $\xi$ are in the interval $a\leq x\leq b$. We define

$$x_{n+1}=x_n+c_nf(x_n) \qquad (n=1, 2, \ldots).$$

Then, if $f'(x)\geq 0$ and the constants $c_n$ are negative and bounded, the sequence $x_n$ converges monotonically to the root $\xi$.

If $c_n=c=\text{constant}<0$ and $f'(x)>0$, then the process converges but not necessarily monotonically.

### Degree of Convergence of an Approximation Process

**3.9.2** Let $x_1$, $x_2$, $x_3$, . . . be an infinite sequence of approximations to a number $\xi$. Then, if

$$|x_{n+1}-\xi|<A|x_n-\xi|^k, \qquad (n=1, 2, \ldots)$$

where $A$ and $k$ are independent of $n$, the sequence is said to have convergence of at most the $k$th degree (or order or index) to $\xi$. If $k=1$ and $A<1$ the convergence is linear; if $k=2$ the convergence is quadratic.

### Regula Falsi (False Position)

**3.9.3** Given $y=f(x)$ to find $\xi$ such that $f(\xi)=0$, choose $x_0$ and $x_1$ such that $f(x_0)$ and $f(x_1)$ have opposite signs and compute

$$x_2=x_1-\frac{(x_1-x_0)}{(f_1-f_0)}f_1=\frac{f_1x_0-f_0x_1}{f_1-f_0}.$$

Then continue with $x_2$ and either of $x_0$ or $x_1$ for which $f(x_0)$ or $f(x_1)$ is of opposite sign to $f(x_2)$.

Regula falsi is equivalent to inverse linear interpolation.

### Method of Iteration (Successive Substitution)

**3.9.4** The iteration scheme $x_{k+1}=F(x_k)$ will converge to a zero of $x=F(x)$ if

$$(1) \quad |F'(x)|\leq q<1 \text{ for } a\leq x\leq b,$$

$$(2) \quad a\leq x_0\pm\frac{|F(x_0)-x_0|}{1-q}\leq b.$$

### Newton's Method of Successive Approximations

**3.9.5**

#### Newton's Rule

If $x=x_k$ is an approximation to the solution $x=\xi$ of $f(x)=0$ then the sequence

$$x_{k+1}=x_k-\frac{f(x_k)}{f'(x_k)}$$

will converge quadratically to $x=\xi$: (if instead of the condition (2) above),

(1) *Monotonic convergence,* $f(x_0)f''(x_0)>0$ and $f'(x)$, $f''(x)$ do not change sign in the interval $(x_0, \xi)$, or

(2) *Oscillatory convergence,* $f(x_0)f''(x_0)<0$ and $f'(x)$, $f''(x)$ do not change sign in the interval $(x_0, x_1)$, $x_0\leq\xi\leq x_1$.

### Newton's Method Applied to Real *n*th Roots

**3.9.6** Given $x^n=N$, if $x_k$ is an approximation $x=N^{1/n}$ then the sequence

$$x_{k+1}=\frac{1}{n}\left[\frac{N}{x_k^{n-1}}+(n-1)x_k\right]$$

will converge quadratically to $x$.

If $n=2$, $x_{k+1}=\frac{1}{2}\left(\frac{N}{x_k}+x_k\right)$,

If $n=3$, $x_{k+1}=\frac{1}{3}\left(\frac{N}{x_k^2}+2x_k\right)$.

### Aitken's $\delta^2$-Process for Acceleration of Sequences

**3.9.7** If $x_k$, $x_{k+1}$, $x_{k+2}$ are three successive iterates in a sequence converging with an error which is approximately in geometric progression, then

$$\bar{x}_k=x_k-\frac{(x_k-x_{k+1})^2}{\Delta^2x_k}=\frac{x_kx_{k+2}-x_{k+1}^2}{\Delta^2x_k};$$

$$\Delta^2x_k=x_k-2x_{k+1}+x_{k+2}$$

is an improved estimate of $x$. In fact, if $x_k=x+$[*] $O(\lambda^k)$ then $\bar{x}=x+O(\lambda^k)$, $|\lambda|<1$.

### 3.10. Theorems on Continued Fractions

**Definitions**

**3.10.1**

(1) Let
$$f=b_0+\cfrac{a_1}{b_1+\cfrac{a_2}{b_2+\cfrac{a_3}{b_3+\cdots}}}$$
$$=b_0+\frac{a_1}{b_1+}\,\frac{a_2}{b_2+}\,\frac{a_3}{b_3+}\cdots$$

If the number of terms is finite, $f$ is called a terminating continued fraction. If the number of terms is infinite, $f$ is called an infinite continued fraction and the terminating fraction

$$f_n=\frac{A_n}{B_n}=b_0+\frac{a_1}{b_1+}\,\frac{a_2}{b_2+}\cdots\frac{a_n}{b_n}$$

is called the $n$th convergent of $f$.

(2) If $\lim\limits_{n\to\infty}\frac{A_n}{B_n}$ exists, the infinite continued fraction $f$ is said to be convergent. If $a_i=1$ and the $b_i$ are integers there is always convergence.

**Theorems**

(1) If $a_i$ and $b_i$ are positive then $f_{2n}<f_{2n+2}$, $f_{2n-1}>f_{2n+1}$.

(2) If $f_n=\frac{A_n}{B_n}$,
$$A_n=b_nA_{n-1}+a_nA_{n-2}$$
$$B_n=b_nB_{n-1}+a_nB_{n-2}$$
where $A_{-1}=1$, $A_0=b_0$, $B_{-1}=0$, $B_0=1$.

(3)
$$\begin{bmatrix}A_n\\B_n\end{bmatrix}=\begin{bmatrix}A_{n-1} & A_{n-2}\\B_{n-1} & B_{n-2}\end{bmatrix}\begin{bmatrix}b_n\\a_n\end{bmatrix}$$

(4)
$$A_nB_{n-1}-A_{n-1}B_n=(-1)^{n-1}\prod_{k=1}^{n}a_k$$

(5) For every $n\geq 0$,
$$f_n=b_0+\frac{c_1a_1}{c_1b_1+}\,\frac{c_1c_2a_2}{c_2b_2+}\,\frac{c_2c_3a_3}{c_3b_3+}\cdots\frac{c_{n-1}c_na_n}{c_nb_n}.$$

(6) $1+b_2+b_2b_3+\ldots+b_2b_3\ldots b_n$
$$=\frac{1}{1-}\,\frac{b_2}{b_2+1-}\,\frac{b_3}{b_3+1-}\cdots\frac{b_n}{-b_n+1}$$
$$\frac{1}{u_1}+\frac{1}{u_2}+\ldots+\frac{1}{u_n}=\frac{1}{u_1-}\,\frac{u_1^2}{u_1+u_2-}\cdots\frac{u_{n-1}^2}{-u_{n-1}+u_n}$$
$$\frac{1}{a_0}-\frac{x}{a_0a_1}+\frac{x^2}{a_0a_1a_2}\cdots+(-1)^n\frac{x^n}{a_0a_1a_2\ldots a_n}$$
$$=\frac{1}{a_0+}\,\frac{a_0x}{a_1-x+}\,\frac{a_1x}{a_2-x+}\cdots\frac{a_{n-1}x}{+a_n-x}$$

## Numerical Methods

### 3.11. Use and Extension of the Tables

**Example 1.** Compute $x^{19}$ and $x^{47}$ for $x=29$ using **Table 3.1.**

$$x^{19}=x^9\cdot x^{10}$$
$$=(1.45071\ 4598\cdot 10^{13})(4.20707\ 2333\cdot 10^{14})$$
$$=6.10326\ 1248\cdot 10^{27}$$
$$x^{47}=(x^{24})^2/x$$
$$=(1.25184\ 9008\cdot 10^{35})^2/29$$
$$=5.40388\ 2547\cdot 10^{68}$$

**Example 2.** Compute $x^{-3/4}$ for $x=9.19826$.

$$(9.19826)^{1/4}=(919.826/100)^{1/4}=(919.826)^{1/4}/10^{\frac{1}{2}}$$

Linear interpolation in **Table 3.1** gives $(919.826)^{1/4}\approx 5.507144$.

By Newton's method for fourth roots with $N=919.826$,

$$\frac{1}{4}\left[\frac{919.826}{(5.507144)^3}+3(5.507144)\right]=5.50714\ 3845$$

Repetition yields the same result. Thus,

$$x^{1/4}=5.50714\ 3845/10^{\frac{1}{2}}=1.74151\ 1796,$$
$$x^{-3/4}=x^{\frac{1}{4}}/x=.18933\ 05683.$$

### 3.12. Computing Techniques

**Example 3.** Solve the quadratic equation $x^2-18.2x+.056$ given the coefficients as $18.2\pm.1$,

$.056 \pm .001$. From **3.8.1** the solution is

$$x=\tfrac{1}{2}(18.\underline{2}\pm[(18.\underline{2})^2-4(.05\underline{6})]^{\frac{1}{2}})$$
$$=\tfrac{1}{2}(18.\underline{2}\pm[33\underline{1.016}]^{\frac{1}{2}})=\tfrac{1}{2}(18.\underline{2}\pm 18.\underline{1939})$$
$$=18.\underline{1969},\ .00\underline{3}$$

The smaller root may be obtained more accurately from

* $$.05\underline{6}/18.\underline{1969}=.003\underline{1}\pm .0001.$$

**Example 4.** Compute $(-3+.0076i)^{\frac{1}{2}}$.

From **3.7.26,** $(-3+.0076i)^{\frac{1}{2}}=u+iv$ where

$$u=\frac{y}{2v},\ v=\left(\frac{r-x}{2}\right)^{\frac{1}{2}},\ r=(x^2+y^2)^{\frac{1}{2}}$$

Thus

$$r=[(-3)^2+(.0076)^2]^{\frac{1}{2}}=(9.00005776)^{\frac{1}{2}}=3.00000\ 9627$$

$$v=\left[\frac{3.00000\ 9627-(-3)}{2}\right]^{\frac{1}{2}}=1.73205\ 2196$$

$$u=\frac{y}{2v}=\frac{.0076}{2(1.73205\ 2196)}=.00219\ 392926$$

We note that the principal square root has been computed.

**Example 5.** Solve the cubic equation $x^3-18.1x-34.8=0$.

To use Newton's method we first form the table of $f(x)=x^3-18.1x-34.8$

| $x$ | $f(x)$ |
|---|---|
| 4 | −43.2 |
| 5 | − .3 |
| 6 | 72.6 |
| 7 | 181.5 |

We obtain by linear inverse interpolation:

$$x_0=5+\frac{0-(-.3)}{72.6-(-.3)}=5.004.$$

Using Newton's method, $f'(x)=3x^2-18.1$ we get

$$x_1\approx x_0-f(x_0)/f'(x_0)$$
$$\approx 5.004-\frac{(-.07215\ 9936)}{57.020048}\approx 5.00526.$$

Repetition yields $x_1=5.00526\ 5097$. Dividing $f(x)$ by $x-5.00526\ 5097$ gives $x^2+5.00526\ 5097x+6.95267\ 869$ the zeros of which are $-2.50263\ 2549 \pm .83036\ 800i$.

**Example 6.** Solve the quartic equation

$$x^4-2.37752\ 4922x^3+6.07350\ 5741x^2$$
$$-11.17938\ 023x+9.05265\ 5259=0.$$

**Resolution Into Quadratic Factors**
$(x^2+p_1x+q_1)(x^2+p_2x+q_2)$
**by Inverse Interpolation**

Starting with the trial value $q_1=1$ we compute successively

| $q_1$ | $q_2=\frac{a_0}{q_1}$ | $p_1=\frac{a_1-a_3q_1}{q_2-q_1}$ | $p_2=a_3-p_1$ | $y(q_1)=q_1+q_2+p_1p_2-a_2$ |
|---|---|---|---|---|
| 1 | 9. 053 | −1. 093 | −1. 284 | 5. 383 |
| 2 | 4. 526 | −2. 543 | . 165 | . 032 |
| 2. 2 | 4. 115 | −3. 106 | . 729 | −2. 023 |

We seek that value of $q_1$ for which $y(q_1)=0$. Inverse interpolation in $y(q_1)$ gives $y(q_1)\approx 0$ for $q_1\approx 2.003$. Then,

| $q_1$ | $q_2$ | $p_1$ | $p_2$ | $y(q_1)$ |
|---|---|---|---|---|
| 2. 003 | 4. 520 | −2. 550 | . 172 | . 011 |

Inverse interpolation between $q_1=2.2$ and $q_1=2.003$ gives $q_1=2.0041$, and thus,

| $q_1$ | $q_2$ | $p_1$ | $p_2$ | $y(q_1)$ |
|---|---|---|---|---|
| 2. 0041 | 4. 51706 7640 | −2. 55259 257 | . 17506 765 | . 00078 552 |
| 2. 0042 | 4. 51684 2260 | −2. 55282 851 | . 17530 358 | . 00001 655 |
| 2. 0043 | 4. 51661 6903 | −2. 55306 447 | . 17553 955 | −. 00075 263 |

Inverse interpolation gives $q_1=2.00420\ 2152$, and we get finally,

| $q_1$ | $q_2$ | $p_1$ | $p_2$ | $y(q_1)$ |
|---|---|---|---|---|
| 2. 00420 2152 | 4. 51683 7410 | −2. 55283 358 | . 17530 8659 | −. 00000 0011 |

(3) Multiply cumulatively $M_1m_0+M_0m_1+31290\ 75681=58812\ 67160\ 12663\ 25894$ and record the digits 12663 25894 in positions 1 to 10.

(4) Transfer the digits 58812 67160 from positions 11 to 20 to positions 1 to 10.

(5) Multiply cumulatively $M_0m_0+58812\ 67160=14116\ 69523\ 40138\ 17612$. The results as obtained are shown below,

$$\begin{array}{r}
96300\ 28346\\
12663\ 25894\phantom{\ 96300\ 28346}\\
\underline{14116\ 69523\ 40138\ 17612\phantom{\ 12663\ 25894\ 96300\ 28346}}\\
14116\ 69523\ 40138\ 17612\ 12663\ 25894\ 96300\ 28346
\end{array}$$

If the product $Mm$ is wanted to 20 digits, only the result obtained in step 5 need be recorded. Further, if the allowable error in the 20th place is a unit, the operation $M_1m_1$ may be omitted. When either of the factors $M$ or $m$ contains less than 20 digits it is convenient to position the numbers as if they both had 20 digits. This multiplication process may be extended to any higher accuracy desired.

**Example 8.** Divide $N=14116\ 69523\ 40138\ 17612$ by $d=20243\ 97459\ 71664\ 32102$.

Method (1)—*linear interpolation.*

$$\begin{array}{r}
N/20243\ 97459\cdot 10^{10}=.69732\ 82430'90519\ 39054\\
N/20243\ 97460\cdot 10^{10}=\underline{.69732\ 82427\ 46057\ 26941}\\
\text{Difference}=3\ 44462\ 12113.
\end{array}$$

Difference $\times .71664\ 32102=24685\ 64402\underline{8}\cdot 10^{-20}$ (note this is an $11\times 10$ multiplication).

Quotient=

$$(69732\ 82430\ 90519\ 39054-246856\ 4402\underline{8})\cdot 10^{-20}$$
$$=.69732\ 82428\ 43662\ 9502\underline{6}$$

There is an error of 3 units in the 20th place due to neglect of the contribution from second differences.

Method (2)—If $N$ and $d$ are numbers each not more than 19 digits let $N=N_1+N_0 10^9$, $d=d_1+d_0 10^9$ where $N_0$ and $d_0$ contain 10 digits and $N_1$ and $d_1$ not more than 9 digits. Then

$$\frac{N}{d}=\frac{N_0 10^9+N_1}{d_0 10^9+d_1}\approx\frac{1}{d_0 10^9}\left[N-\frac{N_0 d_1}{d_0}\right]$$

Here

$N=14116\ 69523\ 40138\ 1761$,

$d=20243\ 97459\ 71664\ 3210$

$N_0=14116\ 69523$, $d_0=20243\ 97459$,

$d_1=71664\ 3210$

(1) $N_0d_1=10116\ 63378\ 42188\ 8830$ (product dial).

(2) $(N_0d_1)/d_0=49973\ 55504$ (quotient dial).

(3) $N-(N_0d_1)/d_0=14116\ 69522\ 90164\ 62106$ (product dial).

(4) $[N-(N_0d_1)/d_0]/d_0 10^9=.69732\ 82428$=first 10 digits of quotient in quotient dial. Remainder $=r=08839\ 11654$, in positions 1 to 10 of product dial.

(5) $r/(d_0 10^9)=.43662\ 9502\cdot 10^{-10}$=next 9 digits of quotient. $N/d=.69732\ 82428\ 43662\ 9502$. This method may be modified to give the quotient of 20 digit numbers. Method (1) may be extended to quotients of numbers containing more than 20 digits by employing higher order interpolation.

**Example 9.** Sum the series $S=1-\frac{1}{2}+\frac{1}{3}-\frac{1}{4}+\ldots$ to 5D using the Euler transform.

The sum of the first 8 terms is .634524 to 6D. If $u_n=1/n$ we get

| $n$ | $u_n$ | $\Delta u_n$ | $\Delta^2 u_n$ | $\Delta^3 u_n$ | $\Delta^4 u_n$ |
|---|---|---|---|---|---|
| 9 | .111111 | | | | |
| | | −11111 | | | |
| 10 | .100000 | | 2020 | | |
| | | −9091 | | −505 | |
| 11 | .090909 | | 1515 | | 156 |
| | | −7576 | | −349 | |
| 12 | .083333 | | 1166 | | |
| | | −6410 | | | |
| 13 | .076923 | | | | |

From **3.6.27** we then obtain

$$S=.634524+\frac{.111111}{2}-\frac{(-.011111)}{2^2}+\frac{.002020}{2^3}-\frac{(-.000505)}{2^4}+\frac{.000156}{2^5}$$

$$=.634524+.055556+.002778+.000253+.000032+.000005$$

$$=.693148$$

($S=\ln 2=.6931472$ to 7D).

**Example 10.** Evaluate the integral $\int_0^\infty \frac{\sin x}{x}\,dx = \frac{\pi}{2}$ to 4D using the Euler transform.

$$\int_0^\infty \frac{\sin x}{x}\,dx = \sum_{k=0}^{\infty} \int_{k\pi}^{(k+1)\pi} \frac{\sin x}{x}\,dx$$

$$= \sum_{k=0}^{\infty} \int_0^{\pi} \frac{\sin (k\pi+t)}{k\pi+t}\,dt = \sum_{k=0}^{\infty} (-1)^k \int_0^{\pi} \frac{\sin t}{k\pi+t}\,dt.$$

Evaluating the integrals in the last sum by numerical integration we get

| $k$ | $\int_0^{\pi} \frac{\sin t}{k\pi+t}\,dt$ | | | | |
|---|---|---|---|---|---|
| 0 | 1.85194 | | | | |
| 1 | .43379 | | | | |
| 2 | .25661 | | | | |
| 3 | .18260 | $\Delta$ | $\Delta^2$ | $\Delta^3$ | $\Delta^4$ |
| 4 | .14180 | | | | |
| | | −2587 | | | |
| 5 | .11593 | | 799 | | |
| | | −1788 | | −321 | |
| 6 | .09805 | | 478 | | 153 |
| | | −1310 | | −168 | |
| 7 | .08495 | | 310 | | |
| | | −1000 | | | |
| 8 | .07495 | | | | |

The sum to $k=3$ is 1.49216. Applying the Euler transform to the remainder we obtain

$$\frac{1}{2}(.14180) - \frac{1}{2^2}(-.02587) + \frac{1}{2^3}(.00799)$$

$$-\frac{1}{2^4}(-.00321) + \frac{1}{2^5}(.00153)$$

$$= .07090 + .00647 + .00100 + .00020 + .00005$$

$$= .07862$$

We obtain the value of the integral as $1.570\underline{78}$ as compared with 1.57080.

**Example 11.** Sum the series $\sum_{k=1}^{\infty} k^{-2} = \frac{\pi^2}{6}$ using the Euler-Maclaurin summation formula.

From **3.6.28** we have for $n=\infty$,

$$\sum_{k=1}^{\infty} k^{-2} = \sum_{k=1}^{10} k^{-2} + \sum_{k=1}^{\infty} (k+10)^{-2}$$

$$= \sum_{k=1}^{10} k^{-2} + \int_0^\infty f(k)\,dk - \frac{1}{2} f_0 - \frac{1}{12} f_0'$$

$$+ \frac{1}{720} f_0''' - \dots$$

where $f(k) = (k+10)^{-2}$. Thus,

$$\sum_{k=1}^{\infty} k^{-2} = 1.54976\,7731 + .1$$

$$- .005 + .00016\,6667 - .00000\,0333$$

$$= 1.64493\,4065,$$

as compared with $\frac{\pi^2}{6} = 1.64493\,4067$.

**Example 12.** Compute

$$\arctan x = \frac{x}{1+}\,\frac{x^2}{3+}\,\frac{4x^2}{5+}\,\frac{9x^2}{7+}\,\dots$$

to 5D for $x=.2$. Here $a_1 = x$, $a_n = (n-1)^2 x^2$ for $n>1$, $b_0 = 0$, $b_n = 2n-1$, $A_{-1} = 1$, $B_{-1} = 0$, $A_0 = 0$, $B_0 = 1$.

For $n \geq 1$

$$\begin{bmatrix} A_n \\ B_n \end{bmatrix} = \begin{vmatrix} A_{n-1} A_{n-2} \\ B_{n-1} B_{n-2} \end{vmatrix} \begin{bmatrix} 2n-1 \\ (n-1)^2 x^2 \end{bmatrix} \quad \frac{A_0}{B_0} = 0$$

$$\begin{bmatrix} A_1 \\ B_1 \end{bmatrix} = \begin{vmatrix} 0 & 1 \\ 1 & 0 \end{vmatrix} \begin{vmatrix} 1 \\ .2 \end{vmatrix} = \begin{vmatrix} .2 \\ 1 \end{vmatrix} \quad \frac{A_1}{B_1} = .2$$

$$\begin{bmatrix} A_2 \\ B_2 \end{bmatrix} = \begin{vmatrix} .2 & 0 \\ 1 & 1 \end{vmatrix} \begin{vmatrix} 3 \\ .04 \end{vmatrix} = \begin{vmatrix} .6 \\ 3.04 \end{vmatrix} \quad \frac{A_2}{B_2} = .197368$$

$$\begin{bmatrix} A_3 \\ B_3 \end{bmatrix} = \begin{vmatrix} .6 & .2 \\ 3.04 & 1 \end{vmatrix} \begin{vmatrix} 5 \\ .16 \end{vmatrix} = \begin{vmatrix} 3.032 \\ 15.36 \end{vmatrix} \quad \frac{A_3}{B_3} = .197396$$

$$\begin{bmatrix} A_4 \\ B_4 \end{bmatrix} = \begin{vmatrix} 3.032 & .6 \\ 15.36 & 3.04 \end{vmatrix} \begin{vmatrix} 7 \\ .36 \end{vmatrix} = \begin{vmatrix} 21.440 \\ 108.6144 \end{vmatrix} \quad \frac{A_4}{B_4} = .197396$$

Note that in carrying out the recurrence method for computing continued fractions the numerators $A_n$ and the denominators $B_n$ must be used as originally computed. The numerators and denominators obtained by reducing $A_n/B_n$ to lower terms must not be used.

The numbers in square brackets at the bottom of the page mean that the maximum error in a linear interpolate is $a \times 10^{-p}$ ($p$ in parentheses), and that to interpolate to the full tabular accuracy $m$ points must be used in Lagrange's and Aitkens methods for the respective functions $n^{1/r}$. *

# 4. Elementary Transcendental Functions

## Logarithmic, Exponential, Circular and Hyperbolic Functions

### Mathematical Properties

### 4.1. Logarithmic Function

**Integral Representation**

**4.1.1** $$\ln z=\int_1^z \frac{dt}{t}$$

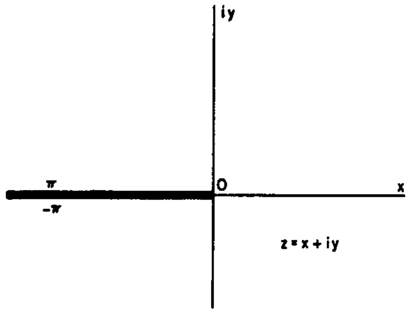

FIGURE 4.1. *Branch cut for* ln *z and* $z^a$.
($a$ not an integer or zero.)

where the path of integration does not pass through the origin or cross the negative real axis. ln $z$ is a single-valued function, regular in the $z$-plane cut along the negative real axis, real when $z$ is positive.

$$z=x+iy=re^{i\theta}.$$

**4.1.2** $$\ln z=\ln r+i\theta \quad (-\pi<\theta\leq\pi).$$

**4.1.3** $$r=(x^2+y^2)^{\frac{1}{2}}, \quad x=r\cos\theta, \quad y=r\sin\theta,$$
$$\theta=\arctan\frac{y}{x}.$$

The general logarithmic function is the many-valued function Ln $z$ defined by

**4.1.4** $$\text{Ln}\, z=\int_1^z \frac{dt}{t}$$

where the path does not pass through the origin.

**4.1.5**
$$\text{Ln}\,(re^{i\theta})=\ln\,(re^{i\theta})+2k\pi i=\ln r+i(\theta+2k\pi),$$

$k$ being an arbitrary integer. ln $z$ is said to be the *principal branch* of Ln $z$.

**Logarithmic Identities**

**4.1.6** $$\text{Ln}\,(z_1z_2)=\text{Ln}\, z_1+\text{Ln}\, z_2.$$

(i.e., every value of Ln $(z_1z_2)$ is one of the values of Ln $z_1$+Ln $z_2$.)

**4.1.7** $$\ln\,(z_1z_2)=\ln z_1+\ln z_2$$
$$(-\pi<\arg z_1+\arg z_2\leq\pi)$$

**4.1.8** $$\text{Ln}\,\frac{z_1}{z_2}=\text{Ln}\, z_1-\text{Ln}\, z_2$$

**4.1.9** $$\ln\frac{z_1}{z_2}=\ln z_1-\ln z_2$$
$$(-\pi<\arg z_1-\arg z_2\leq\pi)$$

**4.1.10** $$\text{Ln}\, z^n=n\,\text{Ln}\, z \qquad (n \text{ integer})$$

**4.1.11** $$\ln z^n=n\ln z$$
$$(n \text{ integer}, \quad -\pi<n\arg z\leq\pi)$$

**Special Values** (see chapter 1)

**4.1.12** $$\ln 1=0$$

**4.1.13** $$\ln 0=-\infty$$

**4.1.14** $$\ln\,(-1)=\pi i$$

**4.1.15** $$\ln\,(\pm i)=\pm\tfrac{1}{2}\pi i$$

**4.1.16** $\ln e=1$, $e$ is the real number such that
$$\int_1^e \frac{dt}{t}=1$$

**4.1.17** $$e=\lim_{n\to\infty}\left(1+\frac{1}{n}\right)^n=2.71828\ 18284\ldots$$
(see **4.2.21**)

**Logarithms to General Base**

**4.1.18** $$\log_a z=\ln z/\ln a$$

**4.1.19** $$\log_a z=\frac{\log_b z}{\log_b a}$$

**4.1.20** $$\log_a b=\frac{1}{\log_b a}$$

**4.1.21** $$\log_e z=\ln z$$

**4.1.22** $$\log_{10} z=\ln z/\ln 10=\log_{10} e\ln z$$
$$=(.43429\quad 44819\ldots)\ln z$$

**4.1.23** $\ln z = \ln 10 \log_{10} z = (2.30258\ 50929\ldots)\log_{10} z$

($\log_e x = \ln x$, called natural, Napierian, or hyperbolic logarithms; $\log_{10} x$, called common or Briggs logarithms.)

**4.1.25** $$\ln z = \left(\frac{z-1}{z}\right) + \frac{1}{2}\left(\frac{z-1}{z}\right)^2 + \frac{1}{3}\left(\frac{z-1}{z}\right)^3 + \ldots \qquad (\Re z \geq \tfrac{1}{2})$$

**4.1.26** $$\ln z = (z-1) - \tfrac{1}{2}(z-1)^2 + \tfrac{1}{3}(z-1)^3 - \ldots \qquad (|z-1| \leq 1, \quad z \neq 0)$$

## 4.4. Inverse Circular Functions

### Definitions

**4.4.1**

$$\arcsin z=\int_0^z\frac{dt}{(1-t^2)^{\frac{1}{2}}}\qquad(z=x+iy)$$

**4.4.2**

$$\arccos z=\int_z^1\frac{dt}{(1-t^2)^{\frac{1}{2}}}=\frac{\pi}{2}-\arcsin z$$

**4.4.3**

$$\arctan z=\int_0^z\frac{dt}{1+t^2}\qquad *$$

The path of integration must not cross the real axis in the case of **4.4.1** and **4.4.2** and the imaginary axis in the case of **4.4.3** except possibly inside the unit circle. Each function is single-valued and regular in the $z$-plane cut along the real axis from $-\infty$ to $-1$ and $+1$ to $+\infty$ in the case of **4.4.1** and **4.4.2** and along the imaginary axis from $i$ to $i\infty$ and $-i$ to $-i\infty$ in the case of **4.4.3**.

Inverse circular functions are also written $\arcsin z=\sin^{-1}z$, $\arccos z=\cos^{-1}z$, $\arctan z=\tan^{-1}z$, . . . .

When $-1\leq x\leq 1$, $\arcsin x$ and $\arccos x$ are real and

**4.4.4** $-\frac{1}{2}\pi\leq\arcsin x\leq\frac{1}{2}\pi,\qquad 0\leq\arccos x\leq\pi$

**4.4.5** $\arctan z+\operatorname{arccot} z=\pm\frac{\pi}{2}\quad\begin{matrix}\mathcal{R}z\geq0\\ \mathcal{R}z<0^{*}\end{matrix}$

**4.4.7** $\operatorname{arcsec} z=\arccos 1/z$

**4.4.8** $\operatorname{arccot} z=\arctan 1/z$

**4.4.9** $\operatorname{arcsec} z+\operatorname{arccsc} z=\frac{1}{2}\pi$

# Numerical Methods

## 4.7. Use and Extension of the Tables

NOTE: In the examples given it is assumed that the arguments are exact.

**Example 1.** Computation of Common Logarithms.

To compute common logarithms, the number must be expressed in the form $x \cdot 10^q$, $(1 \leq x < 10, -\infty \leq q \leq \infty)$. The common logarithm of $x \cdot 10^q$ consists of an integral part which is called the characteristic and a decimal part which is called the mantissa. **Table 4.1** gives the common logarithm of $x$.

| $x$ | $x \cdot 10^q$ | $\log_{10} x \cdot 10^q$ |
|---|---|---|
| .009836 | $9.836 \cdot 10^{-3}$ | $\bar{3}.99281\ 85 = (-2.00718\ 15)$ |
| .09836 | $9.836 \cdot 10^{-2}$ | $\bar{2}.99281\ 85 = (-1.00718\ 15)$ |
| .9836 | $9.836 \cdot 10^{-1}$ | $\bar{1}.99281\ 85 = (-0.00718\ 15)$ |
| 9.836 | $9.836 \cdot 10^{0}$ | 0.99281 85 |
| 98.36 | $9.836 \cdot 10^{1}$ | 1.99281 85 |
| 983.6 | $9.836 \cdot 10^{2}$ | 2.99281 85 |

Interpolation in **Table 4.1** between 983 and 984 gives .99281 85 as the mantissa of 9836.

Note that $\bar{3}.99281\ 85 = -3 + .99281\ 85$. When $q$ is negative the common logarithm can be expressed in the alternative forms

$$\log_{10}(.009836) = \bar{3}.99281\ 85 = 7.99281\ 85\text{–}10$$
$$= -2.00718\ 15.$$

The last form is convenient for conversion from common logarithms to natural logarithms.

The inverse of $\log_{10} x$ is called the antilogarithm of $x$, and is written antilog $x$ or $\log^{-1} x$. The logarithm of the reciprocal of a number is called the cologarithm, written colog.

**Example 2.**

Compute $x^{-3/4}$ for $x = 9.19826$ to 10D using the Table of Common Logarithms.

From **Table 4.1,** four-point Lagrangian interpolation gives $\log_{10}(9.19826) = .96370\ 56812$. Then, $-\frac{3}{4} \log_{10}(x) = -.72277\ 92609 = 9.27722\ 07391 - 10$. Linear inverse interpolation in **Table 4.1** yields antilog $(\bar{1}.27722) = .18933$. For 10 place accuracy subtabulation with 4-point Lagrangian interpolants produces the table

| $N$ | $\log_{10} N$ | $\Delta$ | $\Delta^2$ |
|---|---|---|---|
| .18933 | .27721 94350 | 2 29379 | |
| .18934 | .27724 23729 | 2 29366 | −13 |
| .18935 | .27726 53095 | | |

By linear inverse interpolation

$$x^{-3/4} = .18933\ 05685.$$

**Example 3.**

Convert $\log_{10} x$ to $\ln x$ for $x = .009836$.

Using **4.1.23** and **Table 4.1,** $\ln(.009836) = \ln 10 \log_{10}(.009836) = 2.30258\ 5093\ (-2.00718\ 15) = -4.62170\ 62$.

**Example 4.**

Compute $\ln x$ for $x = .00278$ to 6D.

Using **4.1.7, 4.1.11** and **Table 4.2,** $\ln(.00278) = \ln(.278 \cdot 10^{-2}) = \ln(.278) - 2 \ln 10 = -5.885304$.

Linear interpolation between $x = .002$ and $x = .003$ would give $\ln(.00278) = -5.8\mathit{98}$. To obtain 5 decimal place accuracy with linear interpolation it is necessary that $x > .175$.

**Example 5.**

Compute $\ln x$ for $x = 1131.718$ to 8D.

Using **4.1.7, 4.1.11** and **Table 4.2**

$$\ln 1131.718 = \ln\left(\frac{1131.718}{1131}\ 1131\right)$$
$$= \ln \frac{1131.718}{1131} + \ln 1.131 + \ln 10^3$$
$$= \ln(1.00063\ 4836) + \ln 1.131 + 3 \ln 10.$$

---

*See page II.

Then from **4.1.24**

$$\begin{aligned}\ln\ 1131.718&=(.00063\ 4836)-\tfrac{1}{2}(.00063\ 4836)^2\\&+\ln\ 1.131+3\ln 10=.00063\ 4836-.00000\ 0202\\&+.12310\ 2197+6.90775\ 5279=7.03149\ 211.\end{aligned}$$

**Example 6.**

$$\begin{aligned}a&=\ .00048\ 32583\ 282384\\-\frac{a^2}{2}&=-.\qquad\quad 1167\ 693059\\\frac{a^3}{3}&=\ .\qquad\qquad\quad 376199\\-\frac{a^4}{4}&=-.\qquad\qquad\qquad\ 136\\\ln(1+a)&=\ .00048\ 31415\ 965388\\\ln 1.389&=\ .32858\ 40637\ 722067\\\ln x&=\ .32906\ 72053\ 687455.\end{aligned}$$

**Example 7.**

Compute the principal value of $\ln(\pm2\pm3i)$.
From **4.1.2, 4.1.3** and **Tables 4.2** and **4.14**.

$$\begin{aligned}\ln(2+3i)&=\frac{1}{2}\ln(2^2+3^2)+i\arctan\frac{3}{2}\\&=1.282475+i(.982794)\\\ln(-2+3i)&=\frac{1}{2}\ln 13+i\left(\pi-\arctan\frac{3}{2}\right)\\&=1.282475+i(2.158799)\\\ln(-2-3i)&=\frac{1}{2}\ln 13+i\left(-\pi+\arctan\frac{3}{2}\right)\\&=1.282475-i(2.158799)\\\ln(2-3i)&=\frac{1}{2}\ln 13+i\left(-\arctan\frac{3}{2}\right)\\&=1.282475-i(.982794).\end{aligned}$$

**Example 8.**

Compute $(.227)^{.69}$ to 7D.

**Example 9.**

Compute $e^{4.99728\ 69}$ to 7S.
Using **4.2.18** and **Table 4.4**,

$$e^{4.99728\ 69}=e^{4.9}e^{.09728\ 69}.$$

Linear interpolation gives $e^{.09728\ 69}=1.10217\ 6$ with an error of $1\times10^{-7}$,

$$e^{4.99728\ 69}=(134.28978)(1.10217\ 67)=148.0111.$$

**Example 10.**

Compute $e^x$ to 18D for

$$x=.86725\ 13489\ 24685\ 12693.$$

Let $a=x-.867$. Using **4.2.1**, compute successively

$$\begin{aligned}&1.00000\ \ 00000\ \ 00000\ \ 00000\\a&=.00025\ \ 13489\ \ 24685\ \ 12693\\\frac{a^2}{2!}&=.\qquad\quad\ \ 315\ \ 88140\ \ 97019\\\frac{a^3}{3!}&=.\qquad\qquad\qquad 2646\ \ 54842\\\frac{a^4}{4!}&=.\qquad\qquad\qquad\qquad\ \ 16630\\e^a&=1.00025\ \ 13805\ \ 15472\ \ 81184\\e^{.867}&=2.37976\ \ 08513\ \ 29496\ \ 863\text{ from }\textbf{Table 4.}\\e^ae^{.867}&=e^x=2.38035\ \ 90768\ \ 39006\ \ 089.\end{aligned}$$

**Example 11.**

Compute $e^{648}$ to 7S.

Let $n=\frac{x}{\ln 10}$ and $d=$the decimal part of $\frac{x}{\ln 10}$. Then

$$\begin{aligned}\exp x&=\exp\left(\frac{x}{\ln 10}\ln 10\right)=\exp\,[(n+d)\ln 10]\\&=\exp(\ln 10^n)\exp(d\ln 10)\\&=10^n\exp(d\ln 10)\end{aligned}$$

From **Table 4.4**

$$\begin{aligned}e^{648}&=\exp\left(\frac{648}{\ln 10}\ln 10\right)=\exp(281.42282\ 42\ln 10)\\&=10^{281}\exp(.42282\ 42\ln 10)=10^{281}\exp .97358\ 8\\&=10^{281}(2.647428)=(281)2.647428.\end{aligned}$$

**Example 12.**

Compute $e^{-x}$ for $x=.75$ using the expansion i

Following the procedure in [4.3] we have from **4.2.48**

$$e^{-x}=\sum_{k=0}^{7}A_kT_k^*(x)$$

* where $T_k^*(x)$ are the Chebyshev polynomials defined in chapter **22.** Assuming $b_8=b_9=0$ we generate $b_k$, $k=7, 6, 5, \ldots 0$ from the recurrence relation

$$b_k=(4x-2)b_{k+1}-b_{k+2}+A_k$$

32″=.00015 51 r

38°42′32″=.675598 r.

**Example 14.**

Express $x=1.6789$ radians in degrees, minutes and seconds to the nearest tenth of a second.

From **Table 1.1** giving the mathematical constants we have

$$1\text{ r}=\frac{180°}{\pi}=57.29577\ 95130° \ldots$$

1.6789 r=96.19388°

.19388°×60=11.633′

.633′×60=38.0″

1.6789 r=96°11′38.0″.

**Example 15.**

Compute $\sin x$ and $\cos x$ for $x=2.317$ to 7D.
From **4.3.44** and **Table 4.6**

$$\sin(2.317)=\sin(\pi-2.317)=\sin(.82459\ 2654)$$
$$=.73427\ 12$$

$$\cos(2.317)=\cos(\pi-2.317)=-\cos(.82459\ 2654)$$
$$=-.67885\ 60.$$

Linear interpolation for $x=.82459\ 2654$ gives an error of $9\times10^{-8}$.

**Example 16.**

Compute $\sin x$ for $x=12.867$ to 8D.
From **4.3.16** and **Tables 4.6** and **4.8**

$$\sin(12.867)=\sin 12\cos .867+\cos 12\sin .867$$
$$=.29612\ 142.$$

The method of reduction to an angle in the first quadrant which was given in **Example 15** may also be used.

**Example 17.**

Compute $\sin x$ to 19D for

$$x=.86725\ 13489\ 24685\ 12693.$$

Let $\alpha=.867$, $\beta=x-\alpha$. From **4.3.16** and **Table 4.6**

$$\sin(\alpha+\beta)=\sin\alpha\cos\beta+\cos\alpha\sin\beta$$

$$\sin\alpha=.76239\ 10208\ 07866\ 22598$$

$$\cos\alpha=.64711\ 66288\ 94312\ 75010$$

With the series expansions for $\sin\beta$ and $\cos\beta$ we compute successively

| | | | | |
|---|---|---|---|---|
| | 1.00000 | 00000 | 00000 | 00000 |

This procedure is equivalent to interpolation with Taylor's formula **3.6.4.**

**Example 18.**

In the plane triangle $ABC$, $a=123, B=29°16'$, $c=321$; find $A, b$.

$$b^2=a^2+c^2-2ac\cos B=(123)^2+(321)^2-2(123)(321)\cos 29°16'$$

$$b=221.99934\ 00$$

$$\sin A=\frac{a\sin B}{b}=\frac{(123)(.48887\ 50196)}{221.99934\ 00}=.27086\ 39918$$

$$A=15°42'56.469''.$$

**Example 19.**

In the plane triangle $ABC$, $a=4$, $b=7$, $c=9$, find $A$, $B$, and $C$.

$$\cos A=\frac{c^2+b^2-a^2}{2bc}=\frac{81+49-16}{2\cdot 7\cdot 9}=\frac{114}{126}=.90476\ 1905$$

$$A=.43997\ 5954=25°12'31.6''$$

$$\sin A=.42591\ 7709$$

$$\sin B=\frac{7(.42591\ 7709)}{4},\quad B=.84106\ 8670=48°11'22.9''$$

$$\sin C=\frac{9(.42591\ 7709)}{4},\quad C=1.86054\ 803=106°36'5.6''$$

where the supplementary angle must be chosen for $C$. As a check we get $A+B+C=180°00'.1''$.

**Example 20.**

Compute $\cot x$ for $x=.4589$ to 6D.

Since $x<.5$, using **Table 4.9** with interpolation in $(x^{-1}-\cot x)$, we find $\frac{1}{.4589}-\cot(.4589)=.155159$. Therefore $\cot(.4589)=2.179124-.155159=2.023965$.

**Example 21.**

Compute $\arcsin x$ for $x=.99511$.

For $x>.95$, using **Table 4.14** with interpolation in the auxiliary function $f(x)$ we find

$$\arcsin x=\frac{\pi}{2}-[2(1-x)]^{\frac{1}{2}}f(x)$$

$$\arcsin(.99511)=\frac{\pi}{2}-[2(.00489)]^{\frac{1}{2}}f(.99511)$$

$$=1.57079\ 6327-(.09889\ 388252)(1.00040\ 7951)$$

$$=1.47186\ 2100.$$

**Example 22.**

Compute arctan 20 and arccot 20 to 9D.

Using **4.4.5, 4.4.8,** and **Table 4.14** *

$$\arctan 20=\frac{\pi}{2}-\arctan 1/20=1.52083\ 7931$$

$$\operatorname{arccot} 20=\frac{\pi}{2}-\arctan 20=\arctan .05=.04995\ 8396.$$

**Example 23.**

Express $z=3+9i$ in polar form.

$z=x+iy=re^{i\theta}$, where $r=(x^2+y^2)^{\frac{1}{2}}$,

$\theta=\arctan\frac{y}{x}+2\pi k$, $k$ is an integer. For $k=0$,

$r=(3^2+9^2)^{\frac{1}{2}}=\sqrt{90}=9.486833$

$$\theta=\arctan 9/3=\arctan 3=1.24904\ 58.$$

Thus $3+9i=9.486833\exp(1.24904\ 58i)$.

**Example 24.**

Compute $\arctan x$ for $x=1/3$ to 12D.

From **4.4.34** and **4.4.42** we have

$$\arctan x=\arctan(x_0+h)$$

$$=\arctan x_0+\arctan\frac{h}{1+x_0h+x_0^2}$$

$$=\arctan x_0+\left(\frac{h}{1+x_0h+x_0^2}\right)-\frac{1}{3}\left(\frac{h}{1+x_0h+x_0^2}\right)^3+\ldots.$$

We have

$x=\frac{1}{3}=.33333\ 33333\ 33$ so that $h=.00033\ 33333\ 33$ and, from **Table 4.14,** $\arctan x_0=\arctan .333=.32145\ 05244\ 03$. Since $\frac{h}{1+x_0h+x_0^2}=.00030\ 00300\ 03$ we get

$$\arctan x=.32145\ 05244\ 03+.00030\ 00300\ 03-.00000\ 00000\ 09$$

$$=.32175\ 05543\ 97.$$

If $x$ is given in the form $b/a$ it is convenient to use **4.4.34** in the form

$$\arctan\frac{b}{a}=\arctan x_0+\arctan\frac{b-ax_0}{a+bx_0}.$$

In the present example we get

$$\arctan\frac{1}{3}=\arctan .333+\arctan\frac{1}{3333}.$$

**Example 25.**

Compute arcsec 2.8 to 5D.
Using **4.3.45** and **Table 4.14**

$$\operatorname{arcsec} z=\arcsin \frac{(z^2-1)^{\frac{1}{2}}}{z}$$

$$\operatorname{arcsec} 2.8=\arcsin \frac{[(2.8)^2-1]^{\frac{1}{2}}}{2.8}$$

$$=\arcsin .93404\ 97735$$

$$=1.20559$$

or using **4.3.45** and **Table 4.14**

$$\operatorname{arcsec} z=\arctan (z^2-1)^{\frac{1}{2}}$$

$$\operatorname{arcsec} 2.8=\arctan 2.61533\ 9366$$

$$=\frac{\pi}{2}-\arctan .38235\ 95564,$$

from **4.4.3** and **4.4.8**

$$=1.570796-.365207$$

$$=1.20559.$$

**Example 26.**

Compute arctanh $x$ for $x=.96035$ to 6D.
From **4.6.22** and **Table 4.2**

$$\operatorname{arctanh} .96035=\tfrac{1}{2} \ln \frac{1+.96035}{1-.96035}=\tfrac{1}{2} \ln \frac{1.96035}{.03965}$$

$$=\tfrac{1}{2} \ln 49.44136\ 191$$

$$=\tfrac{1}{2}(3.90078\ 7359)=1.950394.$$

**Example 27.**

Compute arccosh $x$ for $x=1.5368$ to 6D.
Using **Table 4.17**

$$\frac{\operatorname{arccosh} x}{(x^2-1)^{\frac{1}{2}}}=\frac{\operatorname{arccosh} 1.5368}{[(1.5368)^2-1]^{\frac{1}{2}}}=.852346$$

$$\operatorname{arccosh} 1.5368=(.852346)(1.361754)^{\frac{1}{2}}$$

$$=(.852346)(1.166942)$$

$$=.994638.$$

**Example 28.**

Compute arccosh $x$ for $x=31.2$ to 5D.
Using **Tables 4.2** and **4.17** with $1/x=1/31.2$ $=.03205\ 128205$

$$\operatorname{arccosh} 31.2-\ln 31.2=.692886$$

$$\operatorname{arccosh} 31.2=.692886+3.440418=4.13330.$$

$<\lambda>$ = nearest integer to $\lambda$.

For $\lambda^{-1} > .20$, the maximum error in linear interpolation is $(-4)7$; five-point interpolation gives 5D.

For $\lambda^{-1} \leq .20$,

$$x_1 \approx \frac{1}{\sqrt{\lambda}}\left[1 - \frac{1}{6\lambda} + \frac{11}{360\lambda}2 - \frac{1}{432\lambda}3 + \ldots\right].$$

# 5. Exponential Integral and Related Functions

## Mathematical Properties

### 5.1. Exponential Integral

#### Definitions

**5.1.1** $$E_1(z)=\int_z^\infty \frac{e^{-t}}{t}\,dt \qquad (|\arg z|<\pi)$$

**5.1.2** $$\mathrm{Ei}(x)=-\int_{-x}^\infty \frac{e^{-t}}{t}\,dt=\int_{-\infty}^x \frac{e^t}{t}\,dt \qquad (x>0)$$

**5.1.3** $$\mathrm{li}(x)=\int_0^x \frac{dt}{\ln t}=\mathrm{Ei}(\ln x) \qquad (x>1)$$

**5.1.4**

$$E_n(z)=\int_1^\infty \frac{e^{-zt}}{t^n}\,dt \qquad (n=0,1,2,\ldots;\ \mathscr{R}z>0)$$

**5.1.5**

$$\alpha_n(z)=\int_1^\infty t^n e^{-zt}dt \qquad (n=0,1,2,\ldots;\ \mathscr{R}z>0)$$

**5.1.6** $$\beta_n(z)=\int_{-1}^1 t^n e^{-zt}dt \qquad (n=0,1,2,\ldots)$$

In **5.1.1** it is assumed that the path of integration excludes the origin and does not cross the negative real axis.

Analytic continuation of the functions in **5.1.1**, **5.1.2**, and **5.1.4** for $n>0$ yields multi-valued functions with branch points at $z=0$ and $z=\infty$.[3] They are single-valued functions in the $z$-plane cut along the negative real axis.[4] The function li$(z)$, the logarithmic integral, has an additional branch point at $z=1$.

#### Interrelations

**5.1.7**

$$E_1(-x\pm i0)=-\mathrm{Ei}(x)\mp i\pi,$$

$$-\mathrm{Ei}(x)=\tfrac{1}{2}[E_1(-x+i0)+E_1(-x-i0)] \qquad (x>0)$$

#### Explicit Expressions for $\alpha_n(z)$ and $\beta_n(z)$

**5.1.8** $$\alpha_n(z)=n!z^{-n-1}e^{-z}\left(1+z+\frac{z^2}{2!}+\ldots+\frac{z^n}{n!}\right)$$

**5.1.9**

$$\beta_n(z)=n!z^{-n-1}\left\{e^z\left[1-z+\frac{z^2}{2!}-\ldots+(-1)^n\frac{z^n}{n!}\right]\right.$$
$$\left.-e^{-z}\left(1+z+\frac{z^2}{2!}+\ldots+\frac{z^n}{n!}\right)\right\}$$

[3] Some authors [5.14], [5.16] use the entire function $\int_0^z(1-e^{-t})dt/t$ as the basic function and denote it by Ein$(z)$. We have $\mathrm{Ein}(z)=E_1(z)+\ln z+\gamma$.

[4] Various authors define the integral $\int_{-\infty}^z (e^t/t)dt$ in the $z$-plane cut along the positive real axis and denote it also by Ei$(z)$. For $z=x>0$ additional notations such as $\overline{\mathrm{Ei}}(x)$ (e.g., in [5.10], [5.25]), $E^*(x)$ (in [5.2]), Ei*$(x)$ (in [5.6]) are then used to designate the principal value of the integral. Correspondingly, $E_1(x)$ is often denoted by $-\mathrm{Ei}(-x)$.

### Series Expansions

**5.1.10** $$\mathrm{Ei}(x)=\gamma+\ln x+\sum_{n=1}^{\infty}\frac{x^n}{nn!}\qquad (x>0)$$

**5.1.11**
$$E_1(z)=-\gamma-\ln z-\sum_{n=1}^{\infty}\frac{(-1)^n z^n}{nn!}\qquad (|\arg z|<\pi)$$

**5.1.12**
$$E_n(z)=\frac{(-z)^{n-1}}{(n-1)!}[-\ln z+\psi(n)]-\sum_{\substack{m=0\\ m\neq n-1}}^{\infty}{}'\,\frac{(-z)^m}{(m-n+1)m!}$$
$$(|\arg z|<\pi)$$
$$\psi(1)=-\gamma,\ \psi(n)=-\gamma+\sum_{m=1}^{n-1}\frac{1}{m}\qquad (n>1)$$

$\gamma=.57721\ 56649\ \ldots$ is Euler's constant.

### Symmetry Relation

**5.1.16**
$$z\beta_n(z)=(-1)^n e^z-e^{-z}+n\beta_{n-1}(z)\qquad (n=1,2,3,\ldots)$$

**5.1.21**
$$\frac{d}{dx}\left[\frac{E_n(x)}{E_{n-1}(x)}\right]>0\qquad (x>0; n=1,2,3,\ldots)$$

### Continued Fraction

**5.1.22**
$$E_n(z)=e^{-z}\left(\frac{1}{z+}\,\frac{n}{1+}\,\frac{1}{z+}\,\frac{n+1}{1+}\,\frac{2}{z+}\cdots\right)\quad (|\arg z|<\pi)$$

### Special Values

**5.1.23** $$E_n(0)=\frac{1}{n-1}\qquad (n>1)$$

**5.1.24** $$E_0(z)=\frac{e^{-z}}{z}$$

## Numerical Methods

### 5.3. Use and Extension of the Tables

**Example 1.** Compute Ci (.25) to 5D.

From **Tables 5.1** and **4.2** we have

$$\frac{\mathrm{Ci}\,(.25)-\ln(.25)-\gamma}{(.25)^2}=-.249350,$$

$$\mathrm{Ci}\,(.25)=(.25)^2(-.249350)+(-1.38629)$$
$$+.577216=-.82466.$$

**Example 2.** Compute Ei (8) to 5S.

From **Table 5.1** we have $xe^{-x}\mathrm{Ei}\,(x)=1.18185$ for $x=8$. From **Table 4.4**, $e^8=2.98096\times10^3$. Thus Ei $(8)=440.38$.

**Example 3.** Compute Si (20) to 5D.

Since $1/20=.05$ from **Table 5.2** we find $f(20)=.049757$, $g(20)=.002464$. From **Table 4.8,** $\sin 20=.912945$, $\cos 20=.408082$. Using **5.2.8**

$$\mathrm{Si}(20)=\frac{\pi}{2}-f(20)\cos 20-g(20)\sin 20$$
$$=1.570796-.022555=1.54824.$$

**Example 4.** Compute $E_n(x)$, $n=1(1)N$, to 5S for $x=1.275$, $N=10$.

If $x$ is less than about five, the recurrence relation **5.1.14** can be used in increasing order of $n$ without serious loss of accuracy.

By quadratic interpolation in **Table 5.1** we get $E_1(1.275)=.1408099$, and from **Table 4.4**, $e^{-1.275}=.2794310$. The recurrence formula **5.1.14** then yields

---

*See page II.

[8] From C. Hastings, Jr., Approximations for digital computers, Princeton Univ. Press, Princeton, N.J., 1955 (with permission).

| $n$ | $E_n(1.275)$ | | $E_n(1.275)$ |
|---|---|---|---|
| 1 | .1408099 | 6 | .0430168 |
| 2 | .0998984 | 7 | .0374307 |
| 3 | .0760303 | 8 | .0331009 |
| 4 | .0608307 | 9 | .0296534 |
| 5 | .0504679 | 10 | .0268469 |

Interpolating directly in **Table 5.4** for $n=10$ we get $E_{10}(1.275)=.0268470$ as a check.

**Example 5.** Compute $E_n(x)$, $n=1(1)N$, to 5S for $x=10$, $N=10$.

If, as in this example, $x$ is appreciably larger than five and $N\leq x$, then the recurrence relation **5.1.14** may be safely used in decreasing order of $n$([5.5]). From **Table 5.5** for $x^{-1}=.1$ we get $(x+10)e^xE_{10}(x)=1.02436$ so that $E_{10}(10)=2.32529\times 10^{-6}$. Using this as the initial value we obtain column (2).

| $n$ | $10^5E_n(10)$ (1) | $10^5E_n(10)$ (2) |
|---|---|---|
| 1 | .41570 | .41570 |
| 2 | $.3830\underline{0}$ | .38302 |
| 3 | $.355\underline{00}$ | .35488 |

| 5 | $.31\underline{000}$ | .30898 |
| 6 | $.28\underline{800}$ | .29005 |
| 7 | $.27\underline{667}$ | .27325 |
| 8 | $.2\underline{5333}$ | .25822 |
| 9 | $.2\underline{5084}$ | .24472 |
| 10 | $.2\underline{2573}$ | .23253 |

From **Table 5.2** we get $xe^xE_1(x)=.915633$ so that $E_1(10)=4.15697\times 10^{-6}$ as a check. Forward recurrence starting with $E_1(10)=4.1570\times 10^{-6}$ yields the values in column (1). The underlined figures are in error.

**Example 6.** Compute $E_n(x)$, $n=1(1)N$, to 5S for $x=12.3$, $N=20$.

If $N$ is appreciably larger than $x$, and $x$ appreciably larger than five, then the recurrence relation **5.1.14** should be used in the backward direction to generate $E_n(x)$ for $n<n_0$, and in the forward direction to generate $E_n(x)$ for $n>n_0$, where $n_0=\langle x\rangle$.

From **5.1.52**, with $n_0=12$, $x=12.3$, we have

$$E_{n_0}(x)=\frac{e^{-12.3}}{24.3}(1+.02032-.00043-.00001)$$
$$=1.91038\times 10^{-7}.$$

Using the recurrence relation **5.1.14**, as indicated, we get

| $n$ | $10^6E_n(12.3)$ | $10^6E_n(12.3)$ | $n$ |
|---|---|---|---|
| 12 | .191038 | .191038 | 12 |
| 11 | .199213 | .183498 | 13 |
| 10 | .208098 | .176516 | 14 |
| 9 | .217793 | .170042 | 15 |
| 8 | .228406 | .164015 | 16 |
| 7 | .240073 | .158397 | 17 |
| 6 | .252951 | .153144 | 18 |
| 5 | .267234 | .148226 | 19 |
| 4 | .283155 | .143608 | 20 |
| 3 | .300998 | | |
| 2 | .321117 | | |
| 1 | .343953 | | |

From **Tables 5.2** and **5.5** we find $E_1(12.3)=.343953\times 10^{-6}$, $E_{20}(12.3)=.143609\times 10^{-6}$ as a check.

**Example 7.** Compute $\alpha_n(2)$ to 6S for $n=1(1)5$.

The recurrence formula **5.1.15** can be used for all $x>0$ in increasing order of $n$ without loss of accuracy. From **5.1.25** we have $\alpha_0(2)=\frac{1}{2}e^{-2}=.0676676$, so we get

| $n$ | $\alpha_n(2)$ |
|---|---|
| 0 | .0676676 |
| 1 | .101501 |
| 2 | .169169 |
| 3 | .321421 |
| 4 | .710510 |
| 5 | 1.84394 |

Independent calculation with **5.1.8** yields the same result for $\alpha_5(2)$.

The functions $\alpha_0(x)$ and $\alpha_1(x)$ can be obtained from **Table 10.8** using **5.1.48, 5.1.49.**

**Example 8.** Compute $\beta_n(x)$, $n=0(1)N$ to 6S for $x=1$, $N=5$.

Use the recurrence relation **5.1.16** in increasing order of $n$ if

$$x>.368N+.184\ln N+.821$$

and in decreasing order of $n$ otherwise [5.5].

From **5.1.9** with $n=5$ we get $\beta_5(1)=-.324297$ correctly rounded to 6D. Using the recurrence formula **5.1.16** in decreasing order of $n$ and carrying 9D we get the values in column (2).

| $n$ | $\beta_n(1)$ (1) | $\beta_n(1)$ (2) |
|---|---|---|
| 0 | 2.35040 2 | $2.35040\ 238\underline{9}$ |
| 1 | $-.73575\ 9\underline{269}$ | $-.73575\ 888\underline{0}$ |
| 2 | $.87888\ \underline{3849}$ | $.87888\ 462\underline{9}$ |
| 3 | $-.44950\ \underline{9722}$ | $-.44950\ 73\underline{83}$ |
| 4 | $.5523\underline{6\ 3499}$ | $.55237\ 2\underline{854}$ |
| 5 | $-.324\underline{34\ 3774}$ | $-.32429\ 7$ |

Using forward recurrence instead, starting with

$\beta_0(1)=2\sinh 1=2.350402$ and again carrying 9D, we obtain column (1). The underlined figures are in error. The above shows that three significant figures are lost in forward recurrence, whereas about three significant figures are gained in backward recurrence!

An alternative procedure is to start with an arbitrary value for $n$ sufficiently large (see also [5.1]). To illustrate, starting with the value zero at $n=11$ we get

| $n$ | $\beta_n(1)$ | $n$ | $\beta_n(1)$ |
|---|---|---|---|
| 11 | $0.$ | 5 | $-.324297$ |
| 10 | $.28\underline{0560}$ | 4 | $.552373$ |
| 9 | $-.20\underline{6984}$ | 3 | $-.449507$ |
| 8 | $.319\underline{908}$ | 2 | $.878885$ |
| 7 | $-.2538\underline{12}$ | 1 | $-.735759$ |
| 6 | $.40462\underline{1}$ | 0 | $2.350402$ |

The functions $\beta_0(x)$ and $\beta_1(x)$ can be obtained from **Table 10.8** using **5.1.48, 5.1.49.**

**Example 9.** Compute $E_1(z)$ for $z=3.2578+6.8943i$.

From **Table 5.6** we have for $z_0=x_0+iy_0=3+7i$

$$z_0e^{z_0}E_1(z_0)=.934958+.095598i,$$

$$e^{z_0}E_1(z_0)=.059898-.107895i.$$

From Taylor's formula with $f(z)=e^zE_1(z)$ we have

$$f(z)=f(z_0+\Delta z)=f(z_0)+\frac{f'(z_0)}{1!}\Delta z$$
$$+\frac{f''(z_0)}{2!}(\Delta z)^2+\dots$$

with $\Delta z=z-z_0=.2578-.1057i$. Thus with **5.1.27** we get

| $k$ | $f^{(k)}(z_0)/k!$ | | $(\Delta z)^kf^{(k)}(z_0)/k!$ | |
|---|---|---|---|---|
| 0 | $.059898$ | $-.107895i$ | $.059898$ | $-.107895i$ |
| 1 | $.008174$ | $+.012795i$ | $.003460$ | $+.002435i$ |
| 2 | $-.001859$ | $+.000155i$ | $-.000094$ | $+.000110i$ |
| 3 | $.000088$ | $-.000212i$ | $-.000003$ | $-.000004i$ |

$$\begin{aligned} f(z)&=.063261 & &-.105354i\\ e^{-z}&=.031510 & &-.022075i\\ E_1(z)&=-.000332 & &-.004716i \end{aligned}$$

Repeating the calculation with $z_0=3+6i$ and $\Delta z=.2578+.8943i$ we get the same result.

An alternative procedure is to perform bivariate interpolation in the real and imaginary parts of $ze^zE_1(z)$.

**Example 10.** Compute $E_1(z)$ for $z=-4.2+12.7i$.

Using the formula at the bottom of **Table 5.6**

$$e^zE_1(z)\approx\frac{.711093}{-3.784225+12.7i}$$
$$+\frac{.278518}{-1.90572+12.7i}+\frac{.010389}{2.0900+12.7i}$$
$$=-.0184106-.0736698i$$
$$E_1(z)\approx-1.87133-4.70540i.$$

# 6. Gamma Function and Related Functions

## Mathematical Properties

### 6.1. Gamma (Factorial) Function

#### Euler's Integral

**6.1.1** $$\Gamma(z)=\int_0^\infty t^{z-1}e^{-t}\,dt \qquad (\mathscr{R}z>0)$$

$$=k^z\int_0^\infty t^{z-1}e^{-kt}\,dt \qquad (\mathscr{R}z>0,\ \mathscr{R}k>0)$$

#### Euler's Formula

**6.1.2**

$$\Gamma(z)=\lim_{n\to\infty}\frac{n!\,n^z}{z(z+1)\ldots(z+n)} \qquad (z\neq 0,-1,-2,\ldots)$$

#### Euler's Infinite Product

**6.1.3** $$\frac{1}{\Gamma(z)}=ze^{\gamma z}\prod_{n=1}^{\infty}\left[\left(1+\frac{z}{n}\right)e^{-z/n}\right] \qquad (|z|<\infty)$$

$$\gamma=\lim_{m\to\infty}\left[1+\frac{1}{2}+\frac{1}{3}+\frac{1}{4}+\ldots+\frac{1}{m}-\ln m\right]$$

$$=.57721\ 56649\ldots$$

$\gamma$ is known as Euler's constant and is given to 25 decimal places in chapter 1. $\Gamma(z)$ is single valued and analytic over the entire complex plane, save for the points $z=-n(n=0, 1, 2, \ldots)$ where it possesses simple poles with residue $(-1)^n/n!$. Its reciprocal $1/\Gamma(z)$ is an entire function possessing simple zeros at the points $z=-n(n=0, 1, 2, \ldots)$.

#### Hankel's Contour Integral

**6.1.4** $$\frac{1}{\Gamma(z)}=\frac{i}{2\pi}\int_C(-t)^{-z}e^{-t}\,dt \qquad (|z|<\infty)$$

The path of integration $C$ starts at $+\infty$ on the real axis, circles the origin in the counterclockwise direction and returns to the starting point.

#### Factorial and Π Notations

**6.1.5** $$\Pi(z)=z!=\Gamma(z+1)$$

#### Integer Values

**6.1.6** $$\Gamma(n+1)=1\cdot2\cdot3\ldots(n-1)n=n!$$

**6.1.7**

$$\lim_{z\to n}\frac{1}{\Gamma(-z)}=0=\frac{1}{(-n-1)!} \qquad (n=0, 1, 2, \ldots)$$

#### Fractional Values

**6.1.8**

$$\Gamma(\tfrac{1}{2})=2\int_0^\infty e^{-t^2}dt=\pi^{\frac{1}{2}}=1.77245\ 38509\ldots=(-\tfrac{1}{2})!$$

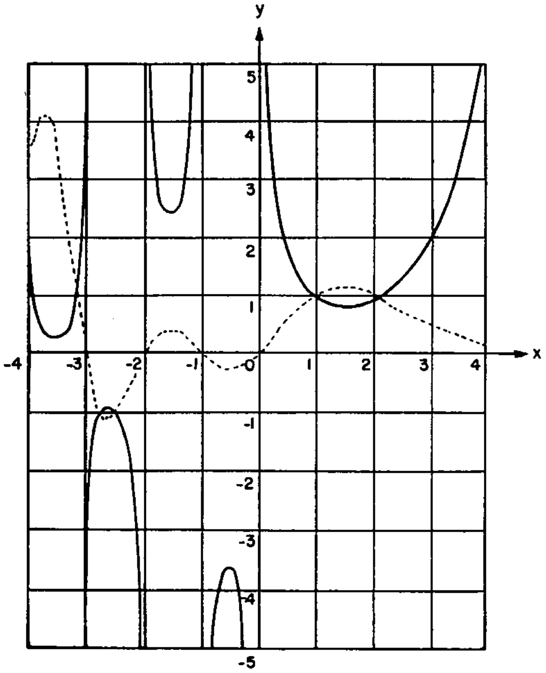

FIGURE 6.1. *Gamma function.* *

———, $y=\Gamma(x)$, – – – –, $y=1/\Gamma(x)$

**6.1.9** $$\Gamma(3/2)=\tfrac{1}{2}\pi^{\frac{1}{2}}=.88622\ 69254\ldots=(\tfrac{1}{2})!$$

**6.1.10** $$\Gamma(n+\tfrac{1}{4})=\frac{1\cdot5\cdot9\cdot13\ldots(4n-3)}{4^n}\Gamma(\tfrac{1}{4})$$

$$\Gamma(\tfrac{1}{4})=3.62560\ 99082\ldots$$

**6.1.11** $$\Gamma(n+\tfrac{1}{3})=\frac{1\cdot4\cdot7\cdot10\ldots(3n-2)}{3^n}\Gamma(\tfrac{1}{3})$$

$$\Gamma(\tfrac{1}{3})=2.67893\ 85347\ldots$$

**6.1.12** $$\Gamma(n+\tfrac{1}{2})=\frac{1\cdot3\cdot5\cdot7\ldots(2n-1)}{2^n}\Gamma(\tfrac{1}{2})$$

**6.1.13** $$\Gamma(n+\tfrac{2}{3})=\frac{2\cdot5\cdot8\cdot11\ldots(3n-1)}{3^n}\Gamma(\tfrac{2}{3})$$

$$\Gamma(\tfrac{2}{3})=1.35411\ 79394\ldots$$

**6.1.14** $$\Gamma(n+\tfrac{3}{4})=\frac{3\cdot7\cdot11\cdot15\ldots(4n-1)}{4^n}\Gamma(\tfrac{3}{4})$$

$$\Gamma(\tfrac{3}{4})=1.22541\ 67024\ \ldots$$

# Numerical Methods

## 6.7. Use and Extension of the Tables

**Example 1.** Compute $\Gamma(6.38)$ to 8S. Using the recurrence relation **6.1.16** and **Table 6.1** we have,

$$\Gamma(6.38)=[(5.38)(4.38)(3.38)(2.38)(1.38)]\Gamma(1.38)$$
$$=232.43671.$$

**Example 2.** Compute $\ln\Gamma(56.38)$, using **Table 6.4** and linear interpolation in $f_2$. We have

$$\ln\Gamma(56.38)=(56.38-\tfrac{1}{2})\ln(56.38)-(56.38)$$
$$+f_2(56.38)$$

The error of linear interpolation in the table of the function $f_2$ is smaller than $10^{-7}$ in this region. Hence, $f_2(56.38)=.92041\ 67$ and $\ln\Gamma(56.38)=169.85497\ 42$.

Direct interpolation in **Table 6.4** of $\log_{10}\Gamma(n)$ eliminates the necessity of employing logarithms. However, the error of linear interpolation is .002 so that $\log_{10}\Gamma(n)$ is obtained with a relative error of $10^{-5}$.

---

*See page II.

**Example 3.** Compute $\psi(6.38)$ to 8S. Using the recurrence relation **6.3.6** and **Table 6.1**.

$$\psi(6.38)=\frac{1}{5.38}+\frac{1}{4.38}+\frac{1}{3.38}+\frac{1}{2.38}+\frac{1}{1.38}+\psi(1.38)$$
$$=1.77275\,59.$$

**Example 4.** Compute $\psi(56.38)$. Using **Table 6.3** we have $\psi(56.38)=\ln 56.38-f_3(56.38)$.

The error of linear interpolation in the table of the function $f_3$ is smaller than $8\times10^{-7}$ in this region. Hence, $f_3(56.38)=.00889\,53$ and $\psi(56.38)=4.023219$.

**Example 5.** Compute $\ln \Gamma(1-i)$. From the reflection principle **6.1.23** and **Table 6.7**, $\ln \Gamma(1-i)=\overline{\ln \Gamma(1+i)}=-.6509+.3016i$.

**Example 6.** Compute $\ln \Gamma(\frac{1}{2}+\frac{1}{2}i)$. Taking the logarithm of the recurrence relation **6.1.15** we have,

$$\begin{aligned}\ln \Gamma(\tfrac{1}{2}+\tfrac{1}{2}i)&=\ln \Gamma(\tfrac{3}{2}+\tfrac{1}{2}i)-\ln(\tfrac{1}{2}+\tfrac{1}{2}i)\\&=-.23419+.03467i\\&\quad-(\tfrac{1}{2}\ln\tfrac{1}{2}+i\arctan 1)\\&=.11239-.75073i\end{aligned}$$

The logarithms of complex numbers are found from **4.1.2**.

**Example 7.** Compute $\ln \Gamma(3+7i)$ using the duplication formula **6.1.18**. Taking the logarithm of **6.1.18**, we have

$$\begin{aligned}-\tfrac{1}{2}\ln 2\pi&=-\;\;.91894\\(\tfrac{5}{2}+7i)\ln 2&=\;\;1.73287+\;\;4.85203i\\\ln\Gamma(\tfrac{3}{2}+\tfrac{7}{2}i)&=-3.31598+\;\;2.32553i\\\ln\Gamma(2+\tfrac{7}{2}i)&=-2.66047+\;\;2.93869i\\\hline\ln\Gamma(3+7i)&=-5.16252+10.11625i\end{aligned}$$

**Example 8.** Compute $\ln \Gamma(3+7i)$ to 5D using the asymptotic formula **6.1.41**. We have

$$\ln(3+7i)=2.03022\,15+1.16590\,45i.$$

Then,

$$\begin{aligned}(2.5+7i)\ln(3+7i)&=-3.0857779+17.1263119i\\-(3+7i)&=-3.0000000-\;\;7.0000000i\\\tfrac{1}{2}\ln(2\pi)&=\;\;\;\;.9189385\\{[12(3+7i)]^{-1}}&=\;\;\;\;.0043103-\;\;\;\;.0100575i\\-[360(3+7i)^3]^{-1}&=\;\;\;\;.0000059-\;\;\;\;.0000022i\\\hline\ln\Gamma(3+7i)&=-5.16252\;\;\;+10.11625i\end{aligned}$$

## 6.8. Summation of Rational Series by Means of Polygamma Functions

An infinite series whose general term is a rational function of the index may always be reduced to a finite series of psi and polygamma functions. The method will be illustrated by writing the explicit formula when the denominator contains a triple root.

Let the general term of an infinite series have the form

$$u_n=\frac{p(n)}{d_1(n)d_2(n)d_3(n)}$$

where

$$d_1(n)=(n+\alpha_1)(n+\alpha_2)\;\ldots\;(n+\alpha_m)$$

$$d_2(n)=(n+\beta_1)^2(n+\beta_2)^2\;\ldots\;(n+\beta_r)^2$$

$$d_3(n)=(n+\gamma_1)^3(n+\gamma_2)^3\;\ldots\;(n+\gamma_s)^3$$

where $p(n)$ is a polynomial of degree $m+2r+3s-2$ at most and where the constants $\alpha_i$, $\beta_i$, and $\gamma_i$ are distinct. Expand $u_n$ in partial fractions as follows

$$u_n=\sum_{k=1}^{m}\frac{a_k}{(n+\alpha_k)}+\sum_{k=1}^{r}\frac{b_{1k}}{(n+\beta_k)}+\frac{b_{2k}}{(n+\beta_k)^2}$$
$$+\sum_{k=1}^{s}\frac{c_{1k}}{(n+\gamma_k)}+\frac{c_{2k}}{(n+\gamma_k)^2}+\frac{c_{3k}}{(n+\gamma_k)^3}$$

$$\sum_{k=1}^{m}a_k+\sum_{k=1}^{r}b_{1k}+\sum_{k=1}^{s}c_{1k}=0.$$

Then, we may express $\sum_{n=1}^{\infty}u_n$ in terms of the constants appearing in this partial fraction expansion as follows

$$\sum_{n=1}^{\infty}u_n=-\sum_{j=1}^{m}a_j\psi(1+\alpha_j)$$
$$-\sum_{j=1}^{r}b_{1j}\psi(1+\beta_j)+\sum_{j=1}^{r}b_{2j}\psi'(1+\beta_j)$$
$$-\sum_{j=1}^{s}c_{1j}\psi(1+\gamma_j)+\sum_{j=1}^{s}c_{2j}\psi'(1+\gamma_j)$$
$$-\sum_{j=1}^{s}\frac{c_{3j}}{2!}\psi''(1+\gamma_j).$$

Higher order repetitions in the denominator are handled similarly. If the denominator contains only simple or double roots, omit the corresponding lines.

**Example 9.** Find

$$s=\sum_{n=1}^{\infty}\frac{1}{(n+1)(2n+1)(4n+1)}.$$

Since

$$\frac{1}{(n+1)(2n+1)(4n+1)}=\frac{\frac{1}{3}}{n+1}-\frac{1}{n+\frac{1}{2}}+\frac{\frac{2}{3}}{n+\frac{1}{4}},$$

we have

$$\alpha_1=1,\ \alpha_2=\tfrac{1}{2},\ \alpha_3=\tfrac{1}{4},\ a_1=\tfrac{1}{3},\ a_2=-1,\ a_3=\tfrac{2}{3}.$$

Thus,

$$s=-\tfrac{1}{3}\psi(2)+\psi(1\tfrac{1}{2})-\tfrac{2}{3}\psi(1\tfrac{1}{4})=.047198.$$

**Example 10.**

Find $s=\sum_{n=1}^{\infty}\frac{1}{n^2(8n+1)^2}.$

Since $\frac{1}{n^2(8n+1)^2}=-\frac{16}{n}+\frac{16}{n+\frac{1}{8}}+\frac{1}{n^2}+\frac{1}{(n+\frac{1}{8})^2}$,

we have,

$$\beta_1=0,\ \beta_2=\tfrac{1}{8},\ b_{11}=-16,\ b_{12}=16,\ b_{21}=1,\ b_{22}=1.$$

Therefore

$$s=16\psi(1)-16\psi(1\tfrac{1}{8})+\psi'(1)+\psi'(1\tfrac{1}{8})=.013499.$$

**Example 11.**

Evaluate $s=\sum_{n=1}^{\infty}\frac{1}{(n^2+1)(n^2+4)}$ (see also **6.3.13**).

We have,

$$\frac{1}{(n^2+1)(n^2+4)}=\frac{i}{6}\left(\frac{1}{n+i}-\frac{1}{n-i}\right)-\frac{i}{12}\left(\frac{1}{n+2i}-\frac{1}{n-2i}\right).$$

Hence, $a_1=\frac{i}{6},\ a_2=\frac{-i}{6},\ a_3=\frac{-i}{12},\ a_4=\frac{i}{12},$

$$\alpha_1=i,\ \alpha_2=-i,\ \alpha_3=2i,\ \alpha_4=-2i,$$

and therefore

$$s=\frac{-i}{6}\,[\psi(1+i)-\psi(1-i)]+\frac{i}{12}\,[\psi(1+2i)-\psi(1-2i)].$$

By **6.3.9**, this reduces to

$$s=\frac{1}{3}\,\mathscr{I}\psi(1+i)-\frac{1}{6}\,\mathscr{I}\psi(1+2i).$$

From **Table 6.8**, $s=.13876$.

Linear interpolation will yield about three figures; eight-point interpolation will yield about eight figures.

For $z$ outside the range of the table, see **Examples 5–8.**

$\mathscr{R}\ln\Gamma(z)=\ln|\Gamma(z)|$ $\mathscr{I}\ln\Gamma(z)=\arg\Gamma(z)$

## Numerical Methods

### 7.5. Use and Extension of the Tables

**Example 1.** Compute erf .745 and $e^{-(.745)^2}$ using Taylor's series.

With the aid of Taylor's theorem and **7.1.19** it can be shown that

$$\operatorname{erf}\,(x_0+ph)=\operatorname{erf} x_0$$

$$+\frac{2}{\sqrt{\pi}}\,e^{-x_0^2}ph\left[1-phx_0+\frac{1}{3}\,p^2h^2(2x_0^2-1)\right]+\epsilon$$

$$e^{-(x_0+ph)^2}=e^{-x_0^2}\left[1-2phx_0+p^2h^2\,(2x_0^2-1)\right.$$

$$\left.-\frac{2}{3}\,p^3h^3x_0(2x_0^2-3)\right]+\eta$$

where $|\epsilon|<1.2\times 10^{-10}$, $|\eta|<3.2\times 10^{-10}$ if $h=10^{-2}$, $|p|\leqq\frac{1}{2}$. With $x_0=.74$, $p=.5$ and using **Table 7.1**

$$\operatorname{erf} .745=.70467\ 80779+(.5)(.00652\ 58247)\times$$

$$[1-(.005)(.74)+(.00000\ 83333)(.0952)]$$

$$=.70792\ 8920$$

$$e^{-(.745)^2}=\frac{\sqrt{\pi}}{2}\,(.65258\ 24665)\,[1-.0074$$

$$+(.000025)(.0952)+(.00000\ 00833)(.74)(1.9048)]$$

$$=.57405\ 7910.$$

As a check the computation was repeated with $x_0=.75$, $p=-.5$.

**Example 2.** Compute erfc $x$ to 5S for $x=4.8$.

We have $1/x^2=.0434028$. With **Table 7.2** and linear interpolation in **Table 7.3**, we obtain

$$\operatorname{erfc} 4.8=\frac{1}{4.8}\,(1.11253)(10^{-10})(.552669)\,\frac{\sqrt{\pi}}{2}$$

$$=(1.1352)10^{-11}.$$

**Example 3.** Compute $e^{-x^2}\int_0^x e^{t^2}dt$ to 5S for $x=6.5$.

With $1/x^2=.0236686$ and linear interpolation in **Table 7.5**

$$e^{-(6.5)^2}\int_0^{6.5} e^{t^2}dt=(.506143)/(6.5)=.077868.$$

**Example 4.** Compute $i^2$ erfc 1.72 using the recurrence relation and **Table 7.1.**

By **7.2.1**, using **Table 7.1,**

$$i^{-1}\text{erfc } 1.72=.05856\ 50.$$

Using the recurrence relation **7.2.5** and **Table 7.1**

$$\begin{aligned} \text{i erfc } 1.72&=-(1.72)(.01499\ 72)+(.5)(.05856\ 50)\\ &=.0034873\\ \text{i}^2\text{ erfc } 1.72&=-(.86)(.0034873)+(.25)(.01499\ 72)\\ &=.0007502. \end{aligned}$$

Note the loss of two significant digits.

**Example 5.** Compute $i^k$ erfc 1.72 for $k=1, 2, 3$ by backward recurrence.

Let the sequence $w_\mu^m(x)\,(\mu=m, m-1, \ldots, 1, 0, -1)$ be generated by backward use of the recurrence relation **7.2.5** starting with $w_{m+2}^m=0$, $w_{m+1}^m=1$. Then, for any fixed $k$, (see [7.7]),

$$\lim_{m\to\infty}\frac{w_k^m(x)}{w_{-1}^m(x)}=\frac{\sqrt{\pi}}{2}\,e^{x^2}\text{i}^k\text{ erfc } x \qquad (x>0).$$

With $x=1.72$, $m=15$ we obtain

| $\mu$ | $w_\mu^{15}(1.72)$ | $\mu$ | $w_\mu^{15}(1.72)$ | $\mu$ | $w_\mu^{15}(1.72)$ | $\mu$ | $w_\mu^{15}(1.72)$ |
|---|---|---|---|---|---|---|---|
| 17 | 0 | 12 | (3) 2.1011 | 7 | (7) 2.5879 | 2 | (11) 1.2920 |
| 16 | 1 | 11 | (4) 1.3831 | 6 | (8) 1.5569 | 1 | (11) 6.0064 |
| 15 | 3.44 | 10 | (4) 9.8005 | 5 | (8) 8.9787 | 0 | (12) 2.5830 |
| 14 | (1) 4.3834 | 9 | (5) 6.4143 | 4 | (9) 4.9570 | −1 | (13) 1.0087 |
| 13 | (2) 2.5399 | 8 | (6) 4.1666 | 3 | (10) 2.6031 | | |

From **Table 7.1** we have $\frac{2}{\sqrt{\pi}}e^{-(1.72)^2}=.058565.$ Thus,

$$\text{i erfc } 1.72\approx(.058565)(6.0064\times10^{11})/1.0087\times10^{13}=3.4873\times10^{-3}$$

$$\text{i}^2\text{ erfc } 1.72\approx(.058565)(1.2920\times10^{11})/1.0087\times10^{13}=7.5013\times10^{-4}$$

$$\text{i}^3\text{ erfc } 1.72\approx(.058565)(2.6031\times10^{10})/1.0087\times10^{13}=1.5114\times10^{-4}.$$

**Example 6.** Compute $C(8.65)$ using **Table 7.8.**

With $x=8.65$, $1/x=.115607$ we have from **Table 7.8** by linear interpolation

$$f(8.65)=.036797,\quad g(8.65)=.000159.$$

From **Table 4.6**

$$\sin\left(\frac{\pi}{2}x^2\right)=-.961382,\quad \cos\left(\frac{\pi}{2}x^2\right)=-.275218.$$

Using **7.3.9**

$$\begin{aligned} C(8.65)=.5+(.036797)(-.961382)&\\ -(.000159)(-.275218)&=.46467. \end{aligned}$$

**Example 7.** Compute $S_1(1.1)$ to 10D.

Using **7.3.8** and **7.3.10** we obtain by 6-pt interpolation in **Table 7.8**

$$\begin{aligned} S_1(1.1)&=S\left(1.1\sqrt{\frac{2}{\pi}}\right)\\ &=S(.87767\ 30169)=.31865\ 57172. \end{aligned}$$

**Example 8.** Compute $S_2(5.24)$ to 6D.

Enter **Table 7.7** in the column headed by $u$. Using Aitken's scheme of interpolation

| $u$ | $S_2(u)$ | | | | | |
|---|---|---|---|---|---|---|
| 5.20310 58 | .43280 06 | .03689 42 | | | | |
| 5.31808 80 | .41573 97 | −.07808 80 | .42732 63 | | | |
| 5.08938 01 | .45093 88 | .15061 99 | 691 63 | .42718 63 | | |
| 5.43432 70 | .39999 44 | −.19432 70 | 756 60 | 6 52 | .42717 71 | |
| 4.97691 11 | .46990 94 | .26308 89 | 674 79 | 9 39 | 61 | .42717 67 |

$$S_2(5.24)=.427177$$

**Example 9.** Compute $S_2(5.24)$ using Taylor's series and **Table 7.8.**

Using **7.3.21** we can write Taylor's series for $f_2(u)=f\left(\sqrt{\frac{2u}{\pi}}\right)$ and $g_2(u)=g\left(\sqrt{\frac{2u}{\pi}}\right)$ in the form

$$f_2(u)=c_0+c_1(u-u_0)+\frac{c_2}{2!}(u-u_0)^2+\frac{c_3}{3!}(u-u_0)^3+\ldots,$$

$$g_2(u)=-\Big[c_1+c_2(u-u_0)+\frac{c_3}{2!}(u-u_0)^2+\frac{c_4}{3!}(u-u_0)^3+\ldots\Big],$$

where

$$c_0=f_2(u_0),\ c_1=-g_2(u_0),$$
$$c_{k+2}=-c_k+(-1)^k\frac{1\cdot 3\ldots(2k-1)}{\sqrt{2\pi u_0}(2u_0)^k}\qquad(k=0,1,2,\ldots).$$

Consulting **Table 7.8** we chose $u_0=1/.185638=5.386819$, thus having $u-u_0=5.24-5.386819=-.146819$. From **Table 7.8**

$$f_2(u_0)=.168270,\quad g_2(u_0)=.014483.$$

Hence, applying the series above,

$$f_2(5.24)=.170436,\quad g_2(5.24)=.015030.$$

Using the 4th formula at the bottom of **Table 7.8**

$$S_2(5.24)=.5-(.170436)(.503471)-(.015030)(-.864012)=.42718.$$

**Example 10.** Compute $S_2(2)$ using **7.3.16.**

Generating the values of $J_{n+\frac{1}{2}}(2)$ as described in chapter **10** we find

$$S_2(2)=J_{3/2}(2)+J_{7/2}(2)+J_{11/2}(2)+J_{15/2}(2)+\ldots=.49129+.06852+.00297+.00006=.56284.$$

**Example 11.** Compute $\int_1^\infty \frac{Y_0(t)}{t}\,dt$ by numerical integration using **Tables 9.1** and **7.8.** [$Y_0(t)$ is the Bessel function of the second kind defined in **9.1.16.**]

We decompose the integral into three parts

$$\int_1^\infty Y_0(t)\frac{dt}{t}=\int_1^{10} Y_0(t)\frac{dt}{t}+\int_{10}^\infty [Y_0(t)-\tilde{Y}_0(t)]\frac{dt}{t}+\int_{10}^\infty \tilde{Y}_0(t)\frac{dt}{t}$$

where

$$\tilde{Y}_0(t)=\left(1-\frac{9}{128t^2}\right)\frac{\sin\left(t-\frac{\pi}{4}\right)}{\sqrt{\frac{1}{2}\pi t}}-\left(1-\frac{75}{128t^2}\right)\frac{\cos\left(t-\frac{\pi}{4}\right)}{8t\sqrt{\frac{1}{2}\pi t}}$$

represents the first two terms of the asymptotic expansion **9.2.2.**

By numerical integration, using **Table 9.1,**

$$\int_1^{10} Y_0(t)\frac{dt}{t}=.41826\ 00.$$

Using the fact that the remainder terms of the asymptotic expansion are less in absolute value than the first neglected terms, we can estimate

$$\left|\int_{10}^\infty [Y_0(t)-\tilde{Y}_0(t)]\frac{dt}{t}\right|\leqq\sqrt{\frac{2}{\pi}}\int_{10}^\infty\left[\frac{3^2\cdot 5^2\cdot 7^2}{2^{12}\cdot 4!}t^{-11/2}+\frac{3^2\cdot 5^2\cdot 7^2\cdot 9^2}{2^{15}\cdot 5!}t^{-13/2}\right]dt=7.33\times 10^{-7}.$$

Finally,

$$\int_{10}^\infty \tilde{Y}_0(t)\frac{dt}{t}=\frac{14659}{6720}\sqrt{2}[1-C_2(10)-S_2(10)]-\frac{5953819}{2688000}\frac{\cos 10-\sin 10}{\sqrt{10\pi}}-\frac{23107}{2150400}\frac{\cos 10+\sin 10}{\sqrt{10\pi}}=-.02298\ 78,$$

using **Tables 7.8** and **4.8.** Hence

$$\int_1^\infty Y_0(t)\frac{dt}{t}=.41826\ 00-.02298\ 78=.39527\ 22.$$

The answer correct to 8D is .39527 290 (**Table 11.2**).

**Example 12.** Compute $w(.44+.67i)$ using bivariate linear interpolation.

By linear interpolation in **Table 7.9** along the $x$-direction at $y=.6$ and $y=.7$

$$w(.44+.6i)\approx .6(.522246+.167880i)+.4(.498591+.202666i)=.512784+.181794i$$

$$w(.44+.7i)\approx .6(.487556+.147975i)+.4(.467521+.179123i)=.479542+.160434i.$$

By linear interpolation along the $y$-direction at $x=.44$

$$w(.44+.67i)\approx .3(.512784+.181794i)+.7(.479542+.160434i)=.489515+.166842i.$$

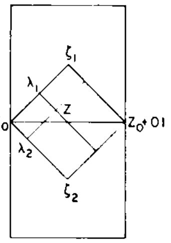
The correct answer is $.489557+.166889i$.

**Example 13.** Compute $\mathscr{R}w(z)$ for $z=.44+.61i$.

Bivariate linear interpolation, as described in **Example 12,** is most accurate if $z$ lies near the center or along a diagonal of one of the squares of the tabular grid [7.6]. It is not as accurate for $z$ near the midpoint of a side of a square, as in this example. However, we may introduce an auxiliary square (see diagram) which contains $z$ close to its center. Bivariate linear interpolation can then be applied within this auxiliary square.

The values of $w(z)$ needed at $z=\zeta_1$, and $z=\zeta_2$ are easily approximated by the average of the four neighboring tabular values. Furthermore the parts to be used are given by

$$\frac{|z_0-\lambda_1|}{|z_0-\zeta_1|}=p_1+p_2,\quad \frac{|z_0-\lambda_2|}{|z_0-\zeta_2|}=p_1-p_2$$



where $z=z_0+.1(p_1+ip_2)$. Thus, with $z_0=.4+.6i$, $\zeta_1=.45+.65i$, $\zeta_2=.45+.55i$, $p_1=.4$, $p_2=.1$, we get from **Table 7.9**

$$\mathscr{R}w(\zeta_1)\approx\tfrac{1}{4}(.522246+.498591+.487556+.467521)$$
$$=.493979$$

$$\mathscr{R}w(\zeta_2)\approx\tfrac{1}{4}(.522246+.498591+.561252+.533157)$$
$$=.528812$$

$$\mathscr{R}w(z)\approx[1-(.4+.1)]\{[1-(.4-.1)].522246$$
$$+(.4-.1).528812\}+(.4+.1)\times$$
$$\{[1-(.4-.1)]\ .493979+(.4-.1).498591\}=.509789.$$

The correct answer is .509756. Straightforward bivariate interpolation gives .509460.

**Example 14.** Compute $\mathscr{I}w(.39+.61i)$ to 6D using Taylor's series.

Let $z=.39+.61i$, $z_0=.4+.6i$. From **7.1.20,** and using **Table 7.9,** we have

$$w(z_0)=.522246+.167880i$$

$$w'(z_0)=-.21634+.36738i,\ z-z_0=(-1+i)10^{-2}$$
$$\tfrac{1}{2}w''(z_0)=-.215-.185i,\ (z-z_0)^2=-2i\times10^{-4}$$

$$\mathscr{I}w(z)=.167880-.0021634-.0036738$$
$$+.0000430=.162086.$$

**Example 15.** Compute $w(.4-1.3i)$.

From **7.1.11, 7.1.12**

$$w(.4-1.3i)=\overline{w(-.4-1.3i)}=2e^{-(.4-1.3i)^2}$$
$$-\overline{w(.4+1.3i)}.$$

Using **Tables 7.9, 4.4** and **4.6**

$$w(.4-1.3i)=4.33342+8.04201i.$$

**Example 16.** Compute $w(7+2i)$.

Using the second formula at the end of **Table 7.9**

$$w(7+2i)=(-2+7i)\left(\frac{.5124242}{44.72474+28i}\right.$$
$$\left.+\frac{.05176536}{42.27525+28i}\right)=.021853+.075010i.$$

**Example 17.** Compute erf $(2+i)$.

From **7.1.3, 7.1.12** we have

$$\operatorname{erf} z=1-e^{-z^2}w(iz)=1-e^{y^2-x^2}(\cos 2xy$$
$$-i\sin 2xy)\overline{w(y+ix)}\qquad (z=x+iy).$$

Using **Tables 7.9, 4.4, 4.6**

$$\operatorname{erf}(2+i)=1-e^{-3}\ (\cos 4-i\sin 4)\overline{w(1+2i)}$$
$$=1.003606-.0112590i.$$

**Example 18.** Compute $S_1\left(\left(\frac{1}{2}+i\right)\sqrt{2}\right)$.

From **7.3.22, 7.3.8, 7.3.18** we have

$$S_1(z)=\frac{1}{2}-\frac{1-i}{4}\ e^{iz^2}w\left[(1+i)\ \frac{z}{\sqrt{2}}\right]$$
$$-\frac{1+i}{4}\ e^{-iz^2}w\left[(i-1)\ \frac{z}{\sqrt{2}}\right].$$

Setting $z=\left(\frac{1}{2}+i\right)\sqrt{2}$ and making use of **7.1.11, 7.1.12,** and **Table 7.9**

$$S_1\left(\left(\frac{1}{2}+i\right)\sqrt{2}\right)=$$
$$-\frac{i}{2}-\frac{1-i}{4}\ e^{-2}\left(\cos\frac{3}{2}-i\sin\frac{3}{2}\right)\overline{w\left(\frac{1}{2}+\frac{3}{2}\,i\right)}$$
$$+\frac{1+i}{4}\ e^{2}\left(\cos\frac{3}{2}+i\sin\frac{3}{2}\right)w\left(\frac{3}{2}+\frac{1}{2}\,i\right)$$
$$=-.990734-.681619i.$$

**Example 19.** Compute $\int_0^\infty e^{-(1/4)t^2-3t}\cos(2t)dt$ using **Table 7.9.**

Setting $b=y+ix$, $c=0$ in **7.4.2** and using **7.1.3, 7.1.12** we find

$$\int_0^\infty e^{-at^2-2yt}\cos(2xt)dt=\frac{1}{2}\sqrt{\frac{\pi}{a}}\,\mathscr{R}w\left(\frac{x+iy}{\sqrt{a}}\right)$$
$$(a>0,x,y\text{ real}).$$

Hence from **Table 7.9**

$$\int_0^\infty e^{-(1/4)t^2-3t}\cos(2t)dt=\sqrt{\pi}\,\mathscr{R}w(2+3i)=.231761.$$

# 8. Legendre Functions

## Mathematical Properties

### Notation

The conventions used are $z=x+iy$, $x$, $y$ real, and in particular, $x$ always means a real number in the interval $-1\leq x\leq +1$ with $\cos\theta=x$ where $\theta$ is likewise a real number; $n$ and $m$ are positive integers or zero; $\nu$ and $\mu$ are unrestricted except where otherwise indicated.

Other notations are:

$$P^n(x) \text{ for } \frac{n!P_n(x)}{(2n-1)!!}$$

$$P_{nm}(x) \text{ for } (-1)^m P_n^m(x)$$

$$T_n^m(x) \text{ for } (-1)^m P_n^m(x)$$

$$\overline{P_n^m}(x) \text{ for } (-1)^m\sqrt{\frac{(2n+1)(n-m)!}{2(n+m)!}}\,P_n^m(x)$$

$$\mathfrak{P}_\nu^\mu(z) \text{ for } P_\nu^\mu(z),\ \mathfrak{Q}_\nu^\mu(z) \text{ for } Q_\nu^\mu(z) \qquad (\mathscr{R}z>1)$$

$$\mathfrak{Q}_\nu^\mu(z) \text{ for } e^{\mu\pi i}Q_\nu^\mu(z)$$

$$Q_\nu^\mu(z) \text{ for } \frac{\sin(\nu+u)\pi}{\sin\nu\pi}\,Q_\nu^\mu(z)$$

Various other definitions of the functions occur as well as mixing of definitions.

### 8.1. Differential Equation

**8.1.1**

$$(1-z^2)\frac{d^2w}{dz^2}-2z\frac{dw}{dz}+[\nu(\nu+1)-\frac{\mu^2}{1-z^2}]w=0$$

**Solutions**

(Degree $\nu$ and order $\mu$ with singularities at $z=\pm 1$, $\infty$ as ordinary branch points—$\mu$, $\nu$ arbitrary complex constants.)

**$P_\nu^\mu(z)$, $Q_\nu^\mu(z)$—Associated Legendre Functions (Spherical Harmonics) of the First and Second Kinds [2]**

$$|\arg(z\pm 1)|<\pi, \qquad |\arg z|<\pi$$

$$(z^2-1)^{\frac{1}{2}\mu}=(z-1)^{\frac{1}{2}\mu}(z+1)^{\frac{1}{2}\mu}$$

(For $P_\nu^\mu(z)$, $\mu=0$, Legendre polynomials, see chapter **22.**)

**8.1.2**

$$P_\nu^\mu(z)=\frac{1}{\Gamma(1-\mu)}\left[\frac{z+1}{z-1}\right]^{\frac{1}{2}\mu}F\left(-\nu,\nu+1;1-\mu;\frac{1-z}{2}\right) \qquad (|1-z|<2)$$

(For $F(a, b; c; z)$ see chapter **15.**)

**8.1.3**
$$Q_\nu^\mu(z)=e^{i\mu\pi}2^{-\nu-1}\pi^{\frac{1}{2}}\frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu+\frac{3}{2})}\,z^{-\nu-\mu-1}(z^2-1)^{\frac{1}{2}\mu}F\left(1+\frac{\nu}{2}+\frac{\mu}{2},\frac{1}{2}+\frac{\nu}{2}+\frac{\mu}{2};\nu+\frac{3}{2};\frac{1}{z^2}\right) \qquad (|z|>1)$$

**Alternate Forms**

(Additional forms may be obtained by means of the transformation formulas of the hypergeometric function, see [8.1].)

**8.1.4**
$$P_\nu^\mu(z)=2^\mu\pi^{\frac{1}{2}}(z^2-1)^{-\frac{1}{2}\mu}\left\{\frac{F\left(-\frac{\nu}{2}-\frac{\mu}{2},\frac{1}{2}+\frac{\nu}{2}-\frac{\mu}{2};\frac{1}{2};z^2\right)}{\Gamma\left(\frac{1}{2}-\frac{\nu}{2}-\frac{\mu}{2}\right)\Gamma\left(1+\frac{\nu}{2}-\frac{\mu}{2}\right)}-2z\,\frac{F\left(\frac{1}{2}-\frac{\nu}{2}-\frac{\mu}{2},1+\frac{\nu}{2}-\frac{\mu}{2};\frac{3}{2};z^2\right)}{\Gamma\left(\frac{1}{2}+\frac{\nu}{2}-\frac{\mu}{2}\right)\Gamma\left(-\frac{\nu}{2}-\frac{\mu}{2}\right)}\right\} \qquad (|z^2|<1)$$

**8.1.5**
$$\begin{aligned}P_\nu^\mu(z)&=\frac{2^{-\nu-1}\pi^{-\frac{1}{2}}\Gamma(-\frac{1}{2}-\nu)z^{-\nu+\mu-1}}{(z^2-1)^{\mu/2}\Gamma(-\nu-\mu)}\,F\left(\frac{1}{2}+\frac{\nu}{2}-\frac{\mu}{2},1+\frac{\nu}{2}-\frac{\mu}{2};\nu+\frac{3}{2};z^{-2}\right)\\&\quad+\frac{2^\nu\Gamma(\frac{1}{2}+\nu)z^{\nu+\mu}}{(z^2-1)^{\mu/2}\Gamma(1+\nu-\mu)}\,F\left(-\frac{\nu}{2}-\frac{\mu}{2},\frac{1}{2}-\frac{\nu}{2}-\frac{\mu}{2};\frac{1}{2}-\nu;z^{-2}\right) \qquad (|z^{-2}|<1)\end{aligned}$$

**8.1.6**

## Numerical Methods

### 8.15. Use and Extension of the Tables

**Computation of $P_n(x)$**

For all values of $x$ there is very little loss of significant figures (except at zeros) in using the recurrence relation **8.5.3** for increasing values of $n$.

**Example 1.** Compute $P_n(x)$ for $x=.31415\ 92654$ and $x=2.6$ for $n=2(1)8$.

| $n$ | $P_n(.31415\ 92654)$ | $P_n(2.6)$ |
|---|---|---|
| 0 | 1 | 1 |
| 1 | .31415 92654 | 2.6 |
| 2 | −.35195 59340 | 9.64 |
| 3 | −.39372 32064 | 40.04 |
| 4 | .04750 63122 | 174.952 |
| 5 | .34184 27517 | 786.74336 |
| 6 | .15729 86975 | 3604.350016 |
| 7 | −.20123 39354 | 16729.51005 |
| 8 | −.25617 29328 | 78402.55522 |

Computing $P_8(x)$ using **Table 22.9** carrying ten significant figures, $P_8(.31415\ 92654)=-.25617\ 2933$ and $P_8(2.6)=78402.55526$.

### Computation of $Q_n(x)$

For $x<1$, use of **8.5.3** for increasing values of $n$ leads to very little loss of significant figures. However, for $x>1$, the recurrence relation **8.5.3** should be used only for decreasing values of $n$, after having first obtained $Q_n$ using the formulas in terms of hypergeometric functions.

**Example 2.** Compute $Q_n(x)$ for $x=.31415\ 92654$ and $n=0(1)4$.

With the aid of **8.4.2** and **8.4.4** we obtain

| $n$ | $Q_n(.31415\ 92654)$ |
|---|---|
| 0 | .32515 34813 |
| 1 | −.89785 00212 |
| 2 | −.58567 85953 |
| 3 | .29190 60854 |
| 4 | .59974 26989 |

Using the results of **Example 1** together with **8.6.19**, we find $Q_4(x)=\frac{1}{2}P_4(x)\ln\left(\frac{1+x}{1-x}\right)-W_3(x)$ where $W_3=\frac{7}{4}P_3+\frac{1}{3}P_1$, giving $Q_4(.31415\ 92654)=.59974\ 26989$.

**Example 3.** Compute $Q_5(x)$ for $x=2.6$.

Ten terms in the series for $F\left(\frac{\nu+2}{2},\frac{\nu+1}{2};\nu+\frac{3}{2};\frac{1}{z^2}\right)$ of **8.1.3** are necessary to obtain nine significant figures giving $Q_5(2.6)=4.8182\ 4468\times10^{-5}$. Using **8.5.3** with increasing values of $n$ carrying ten significant figures we obtain

| $n$ | $Q_n(2.6)$ |
|---|---|
| 0 | .40546 51081 |
| 1 | .05420 928 |
| 2 | .00868 364 |
| 3 | .00148 95 |
| 4 | .00026 49 |
| 5 | .00004 81 |

where $Q_0$ and $Q_1$ are obtained using **8.4.2** and **8.4.4.**

### Computation of $P_{\pm\frac{1}{2}}(x)$, $Q_{\pm\frac{1}{2}}(x)$

For all values of $x$, $P_{\pm\frac{1}{2}}(x)$ and $Q_{\pm\frac{1}{2}}(x)$ are most easily computed by means of **8.13.**

**Example 4.** Compute $Q_{-\frac{1}{2}}(x)$ for $x=2.6$.

Using **8.13.3** and interpolating in **Table 17.1** for $K(.\dot{5})$, we find

$$Q_{-\frac{1}{2}}(2.6)=\sqrt{\frac{2}{x+1}}\,K\left(\sqrt{\frac{2}{x+1}}\right)$$

$$=(.74535\ 59925)(1.90424\ 1417)$$

$$=1.41933\ 7751.$$

On the other hand, at least nine terms in the expansion of $F\left(\frac{\nu+2}{2},\frac{\nu+1}{2};\nu+\frac{3}{2};\frac{1}{z^2}\right)$ of **8.1.3** are necessary to obtain comparable accuracy.

# 9. Bessel Functions of Integer Order

## Mathematical Properties

### Notation

The tables in this chapter are for Bessel functions of integer order; the text treats general orders. The conventions used are:

$z=x+iy$; $x$, $y$ real.

$n$ is a positive integer or zero.

$\nu$, $\mu$ are unrestricted except where otherwise indicated; $\nu$ is supposed real in the sections devoted to Kelvin functions **9.9**, **9.10**, and **9.11**.

The notation used for the Bessel functions is that of Watson [9.15] and the British Association and Royal Society Mathematical Tables. The function $Y_\nu(z)$ is often denoted $N_\nu(z)$ by physicists and European workers.

Other notations are those of:

Aldis, Airey:

$$G_n(z) \text{ for } -\tfrac{1}{2}\pi Y_n(z), K_n(z) \text{ for } (-)^n K_n(z).$$

Clifford:

$$C_n(x) \text{ for } x^{-\frac{1}{2}n} J_n(2\sqrt{x}).$$

Gray, Mathews and MacRobert [9.9]:

$$Y_n(z) \text{ for } \tfrac{1}{2}\pi Y_n(z)+(\ln 2-\gamma)J_n(z),$$

### Bessel Functions $J$ and $Y$

### 9.1. Definitions and Elementary Properties

#### Differential Equation

**9.1.1** $$z^2\frac{d^2w}{dz^2}+z\frac{dw}{dz}+(z^2-\nu^2)w=0$$

Solutions are the Bessel functions of the first kind $J_{\pm\nu}(z)$, of the second kind $Y_\nu(z)$ (also called Weber's function) and of the third kind $H_\nu^{(1)}(z)$, $H_\nu^{(2)}(z)$ (also called the Hankel functions). Each is a regular (holomorphic) function of $z$ throughout the $z$-plane cut along the negative real axis, and for fixed $z(\neq 0)$ each is an entire (integral) function of $\nu$. When $\nu=\pm n$, $J_\nu(z)$ has no branch point and is an entire (integral) function of $z$.

Important features of the various solutions are as follows: $J_\nu(z)(\mathscr{R}\nu\geq 0)$ is bounded as $z\rightarrow 0$ in any bounded range of arg $z$. $J_\nu(z)$ and $J_{-\nu}(z)$ are linearly independent except when $\nu$ is an integer. $J_\nu(z)$ and $Y_\nu(z)$ are linearly independent for all values of $\nu$.

$H_\nu^{(1)}(z)$ tends to zero as $|z|\rightarrow\infty$ in the sector $0<\arg z<\pi$; $H_\nu^{(2)}(z)$ tends to zero as $|z|\rightarrow\infty$ in the sector $-\pi<\arg z<0$. For all values of $\nu$, $H_\nu^{(1)}(z)$ and $H_\nu^{(2)}(z)$ are linearly independent.

#### Relations Between Solutions

**9.1.2** $$Y_\nu(z)=\frac{J_\nu(z)\cos(\nu\pi)-J_{-\nu}(z)}{\sin(\nu\pi)}$$

The right of this equation is replaced by its limiting value if $\nu$ is an integer or zero.

$$\begin{aligned}H_\nu^{(2)}(z)&=J_\nu(z)-iY_\nu(z)\\&=i\csc(\nu\pi)\{J_{-\nu}(z)-e^{\nu\pi i}J_\nu(z)\}\end{aligned}$$

If $\mathscr{C}=J$ and the upper signs are taken, the restriction on $\lambda$ is unnecessary.

**Gegenbauer's**

**9.1.80**

$$\frac{\mathscr{C}_{\nu}(w)}{w^{\nu}}=2^{\nu}\Gamma(\nu)\sum_{k=0}^{\infty}(\nu+k)\frac{\mathscr{C}_{\nu+k}(u)}{u^{\nu}}\frac{J_{\nu+k}(v)}{v^{\nu}}C_k^{(\nu)}(\cos\alpha)$$

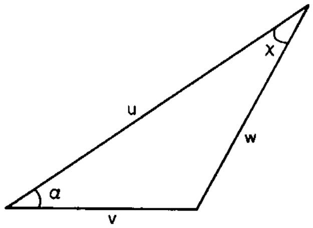
$$(\nu\neq 0,-1,\ldots,|ve^{\pm i\alpha}|<|u|)$$

In **9.1.79** and **9.1.80**,

$$w=\sqrt{(u^2+v^2-2uv\cos\alpha)},$$

$$u-v\cos\alpha=w\cos\chi,\ v\sin\alpha=w\sin\chi$$

the branches being chosen so that $w\rightarrow u$ and $\chi\rightarrow 0$ as $v\rightarrow 0$. $C_k^{(\nu)}(\cos\alpha)$ is Gegenbauer's polynomial (see chapter **22**).



*Gegenbauer's addition theorem.*

If $u, v$ are real and positive and $0\leq\alpha\leq\pi$, then $w, \chi$ are real and non-negative, and the geometrical relationship of the variables is shown in the diagram.

The restrictions $|ve^{\pm i\alpha}|<|u|$ are unnecessary in **9.1.79** when $\mathscr{C}=J$ and $\nu$ is an integer or zero, and in **9.1.80** when $\mathscr{C}=J$.

**Degenerate Form** ($u=\infty$):

**9.1.81**

$$e^{iv\cos\alpha}=\Gamma(\nu)(\tfrac{1}{2}v)^{-\nu}\sum_{k=0}^{\infty}(\nu+k)i^kJ_{\nu+k}(v)C_k^{(\nu)}(\cos\alpha)$$

$$(\nu\neq 0,-1,\ldots)$$

### Neumann's Expansion of an Arbitrary Function in a Series of Bessel Functions

**9.1.82** $$f(z)=a_0J_0(z)+2\sum_{k=1}^{\infty}a_kJ_k(z)\qquad(|z|<c)$$

where $c$ is the distance of the nearest singularity of $f(z)$ from $z=0$,

**9.1.83** $$a_k=\frac{1}{2\pi i}\int_{|z|=c'}f(t)O_k(t)dt\qquad(0<c'<c)$$

and $O_k(t)$ is Neumann's polynomial. The latter is defined by the generating function

**9.1.84**

$$\frac{1}{t-z}=J_0(z)O_0(t)+2\sum_{k=1}^{\infty}J_k(z)O_k(t)\qquad(|z|<|t|)$$

$O_n(t)$ is a polynomial of degree $n+1$ in $1/t$; $O_0(t)=1/t$,

**9.1.85**

$$O_n(t)=\frac{1}{4}\sum_{k=0}^{\leq\frac{1}{2}n}\frac{n(n-k-1)!}{k!}\left(\frac{2}{t}\right)^{n-2k+1}\qquad(n=1,2,\ldots)$$

The more general form of expansion

**9.1.86** $$f(z)=a_0J_{\nu}(z)+2\sum_{k=1}^{\infty}a_kJ_{\nu+k}(z)$$

also called a Neumann expansion, is investigated in [9.7] and [9.15] together with further generalizations. Examples of Neumann expansions are **9.1.41** to **9.1.48** and the Addition Theorems. Other examples are

**9.1.87**

$$\left(\tfrac{1}{2}z\right)^{\nu}=\sum_{k=0}^{\infty}\frac{(\nu+2k)\Gamma(\nu+k)}{k!}J_{\nu+2k}(z)\qquad(\nu\neq 0, -1, -2, \ldots)$$

**9.1.88**

$$Y_n(z)=-\frac{n!\left(\frac{1}{2}z\right)^{-n}}{\pi}\sum_{k=0}^{n-1}\frac{\left(\frac{1}{2}z\right)^{k}J_k(z)}{(n-k)k!}+\frac{2}{\pi}\left\{\ln\left(\tfrac{1}{2}z\right)-\psi(n+1)\right\}J_n(z)-\frac{2}{\pi}\sum_{k=1}^{\infty}(-)^k\frac{(n+2k)J_{n+2k}(z)}{k(n+k)}$$

where $\psi(n)$ is given by **6.3.2.**

**9.1.89**

$$Y_0(z)=\frac{2}{\pi}\left\{\ln\left(\tfrac{1}{2}z\right)+\gamma\right\}J_0(z)-\frac{4}{\pi}\sum_{k=1}^{\infty}(-)^k\frac{J_{2k}(z)}{k}$$

## 9.2. Asymptotic Expansions for Large Arguments

### Principal Asymptotic Forms

When $\nu$ is fixed and $|z|\to\infty$

**9.2.1**

$$J_\nu(z)=\sqrt{2/(\pi z)}\left\{\cos\left(z-\tfrac{1}{2}\nu\pi-\tfrac{1}{4}\pi\right)+e^{|\mathscr{I}z|}O(|z|^{-1})\right\}\qquad(|\arg z|<\pi)$$

**9.2.2**

$$Y_\nu(z)=\sqrt{2/(\pi z)}\left\{\sin\left(z-\tfrac{1}{2}\nu\pi-\tfrac{1}{4}\pi\right)+e^{|\mathscr{I}z|}O(|z|^{-1})\right\}\qquad(|\arg z|<\pi)$$

**9.2.3**

$$H_\nu^{(1)}(z)\sim\sqrt{2/(\pi z)}\,e^{i(z-\frac{1}{2}\nu\pi-\frac{1}{4}\pi)}\qquad(-\pi<\arg z<2\pi)$$

**9.2.4**

$$H_\nu^{(2)}(z)\sim\sqrt{2/(\pi z)}\,e^{-i(z-\frac{1}{2}\nu\pi-\frac{1}{4}\pi)}\qquad(-2\pi<\arg z<\pi)$$

### Hankel's Asymptotic Expansions

When $\nu$ is fixed and $|z|\to\infty$

**9.2.5**

$$J_\nu(z)=\sqrt{2/(\pi z)}\{P(\nu, z)\cos\chi-Q(\nu, z)\sin\chi\}\qquad(|\arg z|<\pi)$$

**9.2.6**

$$Y_\nu(z)=\sqrt{2/(\pi z)}\{P(\nu, z)\sin\chi+Q(\nu, z)\cos\chi\}\qquad(|\arg z|<\pi)$$

**9.2.7**

$$H_\nu^{(1)}(z)=\sqrt{2/(\pi z)}\{P(\nu, z)+iQ(\nu, z)\}e^{i\chi}\qquad(-\pi<\arg z<2\pi)$$

**9.2.8**

$$H_\nu^{(2)}(z)=\sqrt{2/(\pi z)}\{P(\nu, z)-iQ(\nu, z)\}e^{-i\chi}\qquad(-2\pi<\arg z<\pi)$$

where $\chi=z-(\frac{1}{2}\nu+\frac{1}{4})\pi$ and, with $4\nu^2$ denoted by $\mu$,

**9.2.9**

$$P(\nu, z)\sim\sum_{k=0}^{\infty}(-)^k\frac{(\nu, 2k)}{(2z)^{2k}}=1-\frac{(\mu-1)(\mu-9)}{2!(8z)^2}+\frac{(\mu-1)(\mu-9)(\mu-25)(\mu-49)}{4!(8z)^4}-\ldots$$

**9.2.10**

$$Q(\nu, z)\sim\sum_{k=0}^{\infty}(-)^k\frac{(\nu, 2k+1)}{(2z)^{2k+1}}=\frac{\mu-1}{8z}-\frac{(\mu-1)(\mu-9)(\mu-25)}{3!(8z)^3}+\ldots$$

If $\nu$ is real and non-negative and $z$ is positive, the remainder after $k$ terms in the expansion of $P(\nu, z)$ does not exceed the $(k+1)$th term in absolute value and is of the same sign, provided that $k>\frac{1}{2}\nu-\frac{1}{4}$. The same is true of $Q(\nu,z)$ provided that $k>\frac{1}{2}\nu-\frac{3}{4}$.

### Asymptotic Expansions of Derivatives

With the conditions and notation of the preceding subsection

**9.2.11**

$$J_\nu'(z)=\sqrt{2/(\pi z)}\{-R(\nu, z)\sin\chi-S(\nu, z)\cos\chi\}\qquad(|\arg z|<\pi)$$

**9.2.12**

$$Y_\nu'(z)=\sqrt{2/(\pi z)}\{R(\nu, z)\cos\chi-S(\nu, z)\sin\chi\}\qquad(|\arg z|<\pi)$$

**9.2.13**

$$H_\nu^{(1)\prime}(z)=\sqrt{2/(\pi z)}\{iR(\nu, z)-S(\nu, z)\}e^{i\chi}\qquad(-\pi<\arg z<2\pi)$$

**9.2.14**

$$H_\nu^{(2)\prime}(z)=\sqrt{2/(\pi z)}\{-iR(\nu, z)-S(\nu, z)\}e^{-i\chi}\qquad(-2\pi<\arg z<\pi)$$

**9.2.15**

$$R(\nu,z)\sim\sum_{k=0}^{\infty}(-)^k\frac{4\nu^2+16k^2-1}{4\nu^2-(4k-1)^2}\frac{(\nu,2k)}{(2z)^{2k}}$$

$$=1-\frac{(\mu-1)(\mu+15)}{2!(8z)^2}+\ldots$$

**9.2.16**

$$S(\nu,z)\sim\sum_{k=0}^{\infty}(-)^k\frac{4\nu^2+4(2k+1)^2-1}{4\nu^2-(4k+1)^2}\frac{(\nu,2k+1)}{(2z)^{2k+1}}$$

$$=\frac{\mu+3}{8z}-\frac{(\mu-1)(\mu-9)(\mu+35)}{3!(8z)^3}+\ldots$$

### Modulus and Phase

For real $\nu$ and positive $x$

**9.2.17**

$$M_\nu=|H_\nu^{(1)}(x)|=\sqrt{\{J_\nu^2(x)+Y_\nu^2(x)\}}$$
$$\theta_\nu=\arg H_\nu^{(1)}(x)=\arctan\{Y_\nu(x)/J_\nu(x)\}$$

**9.2.18**

$$N_\nu=|H_\nu^{(1)\prime}(x)|=\sqrt{\{J_\nu'^{\,2}(x)+Y_\nu'^{\,2}(x)\}}$$
$$\varphi_\nu=\arg H_\nu^{(1)\prime}(x)=\arctan\{Y_\nu'(x)/J_\nu'(x)\}$$

**9.2.19** $J_\nu(x)=M_\nu\cos\theta_\nu,\qquad Y_\nu(x)=M_\nu\sin\theta_\nu,$

**9.2.20** $J_\nu'(x)=N_\nu\cos\varphi_\nu,\qquad Y_\nu'(x)=N_\nu\sin\varphi_\nu.$

In the following relations, primes denote differentiations with respect to $x$.

**9.2.21** $M_\nu^2\theta_\nu'=2/(\pi x)\qquad N_\nu^2\varphi_\nu'=2(x^2-\nu^2)/(\pi x^3)$

**9.2.22** $N_\nu^2=M_\nu'^2+M_\nu^2\theta_\nu'^2=M_\nu'^2+4/(\pi xM_\nu)^2$

**9.2.23** $(x^2-\nu^2)M_\nu M_\nu'+x^2N_\nu N_\nu'+xN_\nu^2=0$

**9.2.24**

$$\tan(\varphi_\nu-\theta_\nu)=M_\nu\theta_\nu'/M_\nu'=2/(\pi xM_\nu M_\nu')$$
$$M_\nu N_\nu\sin(\varphi_\nu-\theta_\nu)=2/(\pi x)$$

**9.2.25** $x^2M_\nu''+xM_\nu'+(x^2-\nu^2)M_\nu-4/(\pi^2M_\nu^3)=0$

**9.2.26**

$$x^3w'''+x(4x^2+1-4\nu^2)w'+(4\nu^2-1)w=0,\quad w=xM_\nu^2$$

**9.2.27** $$\theta_\nu'^2+\frac{1}{2}\frac{\theta_\nu'''}{\theta_\nu'}-\frac{3}{4}\left(\frac{\theta_\nu''}{\theta_\nu'}\right)^2=1-\frac{\nu^2-\frac{1}{4}}{x^2}$$

### Asymptotic Expansions of Modulus and Phase

When $\nu$ is fixed, $x$ is large and positive, and $\mu=4\nu^2$

**9.2.28**

$$M_\nu^2\sim\frac{2}{\pi x}\left\{1+\frac{1}{2}\frac{\mu-1}{(2x)^2}+\frac{1\cdot3}{2\cdot4}\frac{(\mu-1)(\mu-9)}{(2x)^4}\right.$$
$$\left.+\frac{1\cdot3\cdot5}{2\cdot4\cdot6}\frac{(\mu-1)(\mu-9)(\mu-25)}{(2x)^6}+\ldots\right\}$$

**9.2.29**

$$\theta_\nu\sim x-(\tfrac{1}{2}\nu+\tfrac{1}{4})\pi+\frac{\mu-1}{2(4x)}$$
$$+\frac{(\mu-1)(\mu-25)}{6(4x)^3}+\frac{(\mu-1)(\mu^2-114\mu+1073)}{5(4x)^5}$$
$$+\frac{(\mu-1)(5\mu^3-1535\mu^2+54703\mu-375733)}{14(4x)^7}+\ldots$$

**9.2.30**

$$N_\nu^2\sim\frac{2}{\pi x}\left\{1-\frac{1}{2}\frac{\mu-3}{(2x)^2}-\frac{1\cdot1}{2\cdot4}\frac{(\mu-1)(\mu-45)}{(2x)^4}-\ldots\right\}$$

The general term in the last expansion is given by

$$-\frac{1\cdot1\cdot3\ldots(2k-3)}{2\cdot4\cdot6\ldots(2k)}$$
$$\times\frac{(\mu-1)(\mu-9)\ldots\{\mu-(2k-3)^2\}\{\mu-(2k+1)(2k-1)^2\}}{(2x)^{2k}}$$ *

**9.2.31**

$$\phi_\nu\sim x-(\tfrac{1}{2}\nu-\tfrac{1}{4})\pi+\frac{\mu+3}{2(4x)}+\frac{\mu^2+46\mu-63}{6(4x)^3}$$
$$+\frac{\mu^3+185\mu^2-2053\mu+1899}{5(4x)^5}+\ldots$$

If $\nu\geq0$, the remainder after $k$ terms in **9.2.28** does not exceed the $(k+1)$th term in absolute value and is of the same sign, provided that $k>\nu-\frac{1}{2}$.

In the last two equations $\zeta$ is given by **9.3.38** and **9.3.39** below.

### Uniform Asymptotic Expansions

These are more powerful than the previous expansions of this section, save for **9.3.31** and **9.3.32**, but their coefficients are more complicated. They reduce to **9.3.31** and **9.3.32** when the argument equals the order.

**9.3.35**

$$J_\nu(\nu z)\sim\left(\frac{4\zeta}{1-z^2}\right)^{1/4}\{\frac{\mathrm{Ai}(\nu^{2/3}\zeta)}{\nu^{1/3}}\sum_{k=0}^{\infty}\frac{a_k(\zeta)}{\nu^{2k}}+\frac{\mathrm{Ai}'(\nu^{2/3}\zeta)}{\nu^{5/3}}\sum_{k=0}^{\infty}\frac{b_k(\zeta)}{\nu^{2k}}\}$$

**9.3.36**

$$Y_\nu(\nu z)\sim-\left(\frac{4\zeta}{1-z^2}\right)^{1/4}\{\frac{\mathrm{Bi}(\nu^{2/3}\zeta)}{\nu^{1/3}}\sum_{k=0}^{\infty}\frac{a_k(\zeta)}{\nu^{2k}}+\frac{\mathrm{Bi}'(\nu^{2/3}\zeta)}{\nu^{5/3}}\sum_{k=0}^{\infty}\frac{b_k(\zeta)}{\nu^{2k}}\}$$

**9.3.37**

$$H_\nu^{(1)}(\nu z)\sim2e^{-\pi i/3}\left(\frac{4\zeta}{1-z^2}\right)^{1/4}\{\frac{\mathrm{Ai}(e^{2\pi i/3}\nu^{2/3}\zeta)}{\nu^{1/3}}\sum_{k=0}^{\infty}\frac{a_k(\zeta)}{\nu^{2k}}+\frac{e^{2\pi i/3}\mathrm{Ai}'(e^{2\pi i/3}\nu^{2/3}\zeta)}{\nu^{5/3}}\sum_{k=0}^{\infty}\frac{b_k(\zeta)}{\nu^{2k}}\}$$

When $\nu\rightarrow+\infty$, these expansions hold uniformly with respect to $z$ in the sector $|\arg z|\leq\pi-\epsilon$, where $\epsilon$ is an arbitrary positive number. The corresponding expansion for $H_\nu^{(2)}(\nu z)$ is obtained by changing the sign of $i$ in **9.3.37.**

Here

**9.3.38**

$$\frac{2}{3}\zeta^{3/2}=\int_z^1\frac{\sqrt{1-t^2}}{t}\,dt=\ln\frac{1+\sqrt{1-z^2}}{z}-\sqrt{1-z^2}$$

equivalently,

**9.3.39**

$$\frac{2}{3}(-\zeta)^{3/2}=\int_1^z\frac{\sqrt{t^2-1}}{t}\,dt=\sqrt{z^2-1}-\arccos\left(\frac{1}{z}\right)$$

the branches being chosen so that $\zeta$ is real when $z$ is positive. The coefficients are given by

**9.3.40**

$$a_k(\zeta)=\sum_{s=0}^{2k}\mu_s\zeta^{-3s/2}u_{2k-s}\{(1-z^2)^{-\frac{1}{2}}\}$$

$$b_k(\zeta)=-\zeta^{-\frac{1}{2}}\sum_{s=0}^{2k+1}\lambda_s\zeta^{-3s/2}u_{2k-s+1}\{(1-z^2)^{-\frac{1}{2}}\}$$

where $u_k$ is given by **9.3.9** and **9.3.10,** $\lambda_0=\mu_0=1$ and

**9.3.41**

$$\lambda_s=\frac{(2s+1)(2s+3)\ldots(6s-1)}{s!(144)^s},\qquad \mu_s=-\frac{6s+1}{6s-1}\lambda_s$$

Thus $a_0(\zeta)=1$,

**9.3.42**

$$b_0(\zeta)=-\frac{5}{48\zeta^2}+\frac{1}{\zeta^{\frac{1}{2}}}\{\frac{5}{24(1-z^2)^{3/2}}-\frac{1}{8(1-z^2)^{\frac{1}{2}}}\}$$

$$=-\frac{5}{48\zeta^2}+\frac{1}{(-\zeta)^{\frac{1}{2}}}\{\frac{5}{24(z^2-1)^{3/2}}+\frac{1}{8(z^2-1)^{\frac{1}{2}}}\}$$

Tables of the early coefficients are given below. For more extensive tables of the coefficients and for bounds on the remainder terms in **9.3.35** and **9.3.36** see [9.38].

## 9.5. Zeros

### Real Zeros

When $\nu$ is real, the functions $J_\nu(z)$, $J'_\nu(z)$, $Y_\nu(z)$ and $Y'_\nu(z)$ each have an infinite number of real zeros, all of which are simple with the possible exception of $z=0$. For *non-negative* $\nu$ the $s$th positive zeros of these functions are denoted by $j_{\nu,s}$, $j'_{\nu,s}$, $y_{\nu,s}$ and $y'_{\nu,s}$ respectively, except that $z=0$ is counted as the first zero of $J'_0(z)$. Since $J'_0(z)=-J_1(z)$, it follows that

**9.5.1** $$j'_{0,1}=0,\qquad j'_{0,s}=j_{1,s-1}\qquad(s=2,3,\ldots)$$

The zeros interlace according to the inequalities

**9.5.2**

$$j_{\nu,1}<j_{\nu+1,1}<j_{\nu,2}<j_{\nu+1,2}<j_{\nu,3}<\ldots$$

$$y_{\nu,1}<y_{\nu+1,1}<y_{\nu,2}<y_{\nu+1,2}<y_{\nu,3}<\ldots$$

$$\nu\leq j'_{\nu,1}<y_{\nu,1}<y'_{\nu,1}<j_{\nu,1}<j'_{\nu,2}<y_{\nu,2}<y'_{\nu,2}<j_{\nu,2}<j'_{\nu,3}<\ldots$$

The positive zeros of any two real distinct cylinder functions of the same order are interlaced, as are the positive zeros of any real cylinder function $\mathscr{C}_\nu(z)$, defined as in **9.1.27,** and the contiguous function $\mathscr{C}_{\nu+1}(z)$.

If $\rho_\nu$ is a zero of the cylinder function

**9.5.3** $$\mathscr{C}_\nu(z)=J_\nu(z)\cos(\pi t)+Y_\nu(z)\sin(\pi t)$$

where $t$ is a parameter, then

**9.5.4** $$\mathscr{C}'_\nu(\rho_\nu)=\mathscr{C}_{\nu-1}(\rho_\nu)=-\mathscr{C}_{\nu+1}(\rho_\nu)$$

If $\sigma_\nu$ is a zero of $\mathscr{C}'_\nu(z)$ then

**9.5.5** $$\mathscr{C}_\nu(\sigma_\nu)=\frac{\sigma_\nu}{\nu}\mathscr{C}_{\nu-1}(\sigma_\nu)=\frac{\sigma_\nu}{\nu}\mathscr{C}_{\nu+1}(\sigma_\nu)$$

The parameter $t$ may be regarded as a continuous variable and $\rho_\nu$, $\sigma_\nu$ as functions $\rho_\nu(t)$, $\sigma_\nu(t)$ of $t$. If these functions are fixed by

**9.5.6** $$\rho_\nu(0)=0,\qquad\sigma_\nu(0)=j'_{\nu,1}$$

then

**9.5.7**

$$j_{\nu,s}=\rho_\nu(s),\qquad y_{\nu,s}=\rho_\nu(s-\tfrac{1}{2})\qquad(s=1,2,\ldots)$$

**9.5.8**

$$j'_{\nu,s}=\sigma_\nu(s-1),\qquad y'_{\nu,s}=\sigma_\nu(s-\tfrac{1}{2})\qquad(s=1,2,\ldots)$$

**9.5.9** $$\mathscr{C}'_\nu(\rho_\nu)=\left(\frac{\rho_\nu}{2}\frac{d\rho_\nu}{dt}\right)^{-\frac{1}{2}},\ \mathscr{C}_\nu(\sigma_\nu)=\left(\frac{\sigma_\nu^2-\nu^2}{2\sigma_\nu}\frac{d\sigma_\nu}{dt}\right)^{-\frac{1}{2}}$$

### Infinite Products

**9.5.10** $$J_\nu(z)=\frac{(\frac{1}{2}z)^\nu}{\Gamma(\nu+1)}\prod_{s=1}^{\infty}\left(1-\frac{z^2}{j_{\nu,s}^2}\right)$$

**9.5.11** $$J'_\nu(z)=\frac{(\frac{1}{2}z)^{\nu-1}}{2\Gamma(\nu)}\prod_{s=1}^{\infty}\left(1-\frac{z^2}{j'^2_{\nu,s}}\right)\qquad(\nu>0)$$

### McMahon's Expansions for Large Zeros

When $\nu$ is fixed, $s>>\nu$ and $\mu=4\nu^2$

**9.5.12**

$$j_{\nu,s}, y_{\nu,s} \sim \beta - \frac{\mu-1}{8\beta} - \frac{4(\mu-1)(7\mu-31)}{3(8\beta)^3} - \frac{32(\mu-1)(83\mu^2-982\mu+3779)}{15(8\beta)^5} - \frac{64(\mu-1)(6949\mu^3-1\,53855\mu^2+15\,85743\mu-62\,77237)}{105(8\beta)^7} - \dots$$

where $\beta=(s+\frac{1}{2}\nu-\frac{1}{4})\pi$ for $j_{\nu,s}$, $\beta=(s+\frac{1}{2}\nu-\frac{3}{4})\pi$ for $y_{\nu,s}$. With $\beta=(t+\frac{1}{2}\nu-\frac{1}{4})\pi$, the right of **9.5.12** is the asymptotic expansion of $\rho_\nu(t)$ for large $t$.

**9.5.13**

$$j'_{\nu,s}, y'_{\nu,s} \sim \beta' - \frac{\mu+3}{8\beta'} - \frac{4(7\mu^2+82\mu-9)}{3(8\beta')^3} - \frac{32(83\mu^3+2075\mu^2-3039\mu+3537)}{15(8\beta')^5} - \frac{64(6949\mu^4+2\,96492\mu^3-12\,48002\mu^2+74\,14380\mu-58\,53627)}{105(8\beta')^7} - \dots$$

where $\beta'=(s+\frac{1}{2}\nu-\frac{3}{4})\pi$ for $j'_{\nu,s}$, $\beta'=(s+\frac{1}{2}\nu-\frac{1}{4})\pi$ for $y'_{\nu,s}$, $\beta'=(t+\frac{1}{2}\nu+\frac{1}{4})\pi$ for $\sigma_\nu(t)$. For higher terms in **9.5.12** and **9.5.13** see [9.4] or [9.40].

Corresponding expansions for $s=2$, 3 are given in [9.40]. These expansions become progressively weaker as $s$ increases; those which follow do not suffer from this defect.

where $a_s$, $a'_s$ are the $s$th negative zeros of $\mathrm{Ai}(z)$, $\mathrm{Ai}'(z)$ (see **10.4**), $z=z(\zeta)$ is the inverse function defined implicitly by **9.3.39**, and

**9.5.26**

$$h(\zeta)=\{4\zeta/(1-z^2)\}^{\frac{1}{4}}$$
$$f_1(\zeta)=\tfrac{1}{2}z(\zeta)\{h(\zeta)\}^2 b_0(\zeta)$$
$$g_1(\zeta)=\tfrac{1}{2}\zeta^{-1}z(\zeta)\{h(\zeta)\}^2 c_0(\zeta)$$

where $b_0(\zeta)$, $c_0(\zeta)$ appear in **9.3.42** and **9.3.46.** Tables of the leading coefficients follow. More extensive tables are given in [9.40].

The expansions of $y_{\nu,s}$, $Y'_\nu(y_{\nu,s})$, $y'_{\nu,s}$ and $Y_\nu(y'_{\nu,s})$ corresponding to **9.5.22** to **9.5.25** are obtained by changing the symbols $j$, $J$, Ai, Ai′, $a_s$ and $a'_s$ to $y$, $Y$, −Bi, −Bi′, $b_s$ and $b'_s$ respectively.

### Complex Zeros of $J_\nu(z)$

When $\nu\geq-1$ the zeros of $J_\nu(z)$ are all real. If $\nu<-1$ and $\nu$ is not an integer the number of complex zeros of $J_\nu(z)$ is twice the integer part of $(-\nu)$; if the integer part of $(-\nu)$ is odd two of these zeros lie on the imaginary axis.

If $\nu\geq0$, all zeros of $J'_\nu(z)$ are real.

### Complex Zeros of $Y_\nu(z)$

When $\nu$ is real the pattern of the complex zeros of $Y_\nu(z)$ and $Y'_\nu(z)$ depends on the non-integer part of $\nu$. Attention is confined here to the case $\nu=n$, a positive integer or zero.

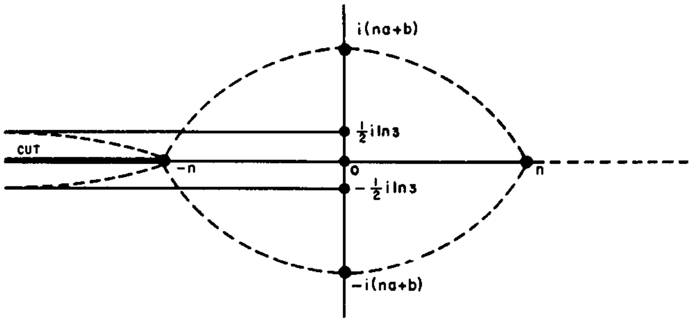

FIGURE 9.5. *Zeros of* $Y_n(z)$ *and* $Y'_n(z)$ . . . $|\arg z| \leq \pi$.

**Figure 9.5** shows the approximate distribution of the complex zeros of $Y_n(z)$ in the region $|\arg z| \leq \pi$. The figure is symmetrical about the real axis. The two curves on the left extend to infinity, having the asymptotes

$$\mathscr{I}z = \pm \tfrac{1}{2} \ln 3 = \pm .54931 \ldots$$

There are an infinite number of zeros near each of these curves.

The two curves extending from $z=-n$ to $z=n$ and bounding an eye-shaped domain intersect the imaginary axis at the points $\pm i(na+b)$, where

$$a = \sqrt{t_0^2 - 1} = .66274 \ldots$$

$$b = \tfrac{1}{2}\sqrt{1 - t_0^{-2}} \ln 2 = .19146 \ldots$$

and $t_0 = 1.19968 \ldots$ is the positive root of $\coth t = t$. There are $n$ zeros near each of these curves. Asymptotic expansions of these zeros for large $n$ are given by the right of **9.5.22** with $\nu = n$ and $\zeta = n^{-2/3}\beta_s$ or $n^{-2/3}\bar{\beta}_s$, where $\beta_s$, $\bar{\beta}_s$ are the complex zeros of $\mathrm{Bi}(z)$ (see **10.4**).

**Figure 9.5** is also applicable to the zeros of $Y'_n(z)$. There are again an infinite number near the infinite curves, and $n$ near each of the finite curves. Asymptotic expansions of the latter for large $n$ are given by the right of **9.5.24** with $\nu = n$ and $\zeta = n^{-2/3}\beta'_s$ or $n^{-2/3}\bar{\beta}'_s$; where $\beta'_s$ and $\bar{\beta}'_s$ are the complex zeros of $\mathrm{Bi}'(z)$.

Numerical values of the three smallest complex zeros of $Y_0(z)$, $Y_1(z)$ and $Y'_1(z)$ in the region $0 < \arg z < \pi$ are given below.

For further details see [9.36] and [9.13]. The latter reference includes tables to facilitate computation.

### Complex Zeros of the Hankel Functions

The approximate distribution of the zeros of $H_n^{(1)}(z)$ and its derivative in the region $|\arg z| \leq \pi$ is indicated in a similar manner on **Figure 9.6.**

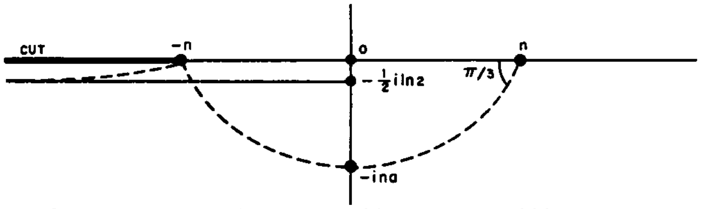

FIGURE 9.6. *Zeros of* $H_n^{(1)}(z)$ *and* $H_n^{(1)\prime}(z)$ . . . $|\arg z| \leq \pi$.

The asymptote of the solitary infinite curve is given by

$$\mathscr{I}z = -\tfrac{1}{2} \ln 2 = -.34657 \ldots$$

There are $n$ zeros of each function near the finite curve extending from $z=-n$ to $z=n$; the asymptotic expansions of these zeros for large $n$ are given by the right side of **9.5.22** or **9.5.24** with $\nu=n$ and $\zeta=e^{-2\pi i/3}n^{-2/3}a_s$ or $\zeta=e^{-2\pi i/3}n^{-2/3}a'_s$.

### Zeros of Cross-Products

If $\nu$ is real and $\lambda$ is positive, the zeros of the function

**9.5.27** $$J_\nu(z)Y_\nu(\lambda z)-J_\nu(\lambda z)Y_\nu(z)$$

are real and simple. If $\lambda>1$, the asymptotic expansion of the $s$th zero is

**9.5.28** $$\beta+\frac{p}{\beta}+\frac{q-p^2}{\beta^3}+\frac{r-4pq+2p^3}{\beta^5}+\ldots$$

where with $4\nu^2$ denoted by $\mu$,

**9.5.29**
$$\beta=s\pi/(\lambda-1)$$
$$p=\frac{\mu-1}{8\lambda},\qquad q=\frac{(\mu-1)(\mu-25)(\lambda^3-1)}{6(4\lambda)^3(\lambda-1)}$$
$$r=\frac{(\mu-1)(\mu^2-114\mu+1073)(\lambda^5-1)}{5(4\lambda)^5(\lambda-1)}$$

The asymptotic expansion of the large positive zeros (not necessarily the $s$th) of the function

**9.5.30** $$J'_\nu(z)Y'_\nu(\lambda z)-J'_\nu(\lambda z)Y'_\nu(z)\qquad(\lambda>1)$$

is given by **9.5.28** with the same value of $\beta$, but instead of **9.5.29** we have

**9.5.31**
$$p=\frac{\mu+3}{8\lambda},\qquad q=\frac{(\mu^2+46\mu-63)(\lambda^3-1)}{6(4\lambda)^3(\lambda-1)}$$
$$r=\frac{(\mu^3+185\mu^2-2053\mu+1899)(\lambda^5-1)}{5(4\lambda)^5(\lambda-1)}$$

The asymptotic expansion of the large positive zeros of the function

**9.5.32** $$J'_\nu(z)Y_\nu(\lambda z)-Y'_\nu(z)J_\nu(\lambda z)$$

is given by **9.5.28** with

**9.5.33**
$$\beta=(s-\tfrac{1}{2})\pi/(\lambda-1)$$
$$p=\frac{(\mu+3)\lambda-(\mu-1)}{8\lambda(\lambda-1)}$$
$$q=\frac{(\mu^2+46\mu-63)\lambda^3-(\mu-1)(\mu-25)}{6(4\lambda)^3(\lambda-1)}$$
$$5(4\lambda)^5(\lambda-1)r=(\mu^3+185\mu^2-2053\mu+1899)\lambda^5-(\mu-1)(\mu^2-114\mu+1073)$$

## Modified Bessel Functions $I$ and $K$

## 9.6. Definitions and Properties

### Differential Equation

**9.6.1** $$z^2\frac{d^2w}{dz^2}+z\frac{dw}{dz}-(z^2+\nu^2)w=0$$

Solutions are $I_{\pm\nu}(z)$ and $K_\nu(z)$. Each is a regular function of $z$ throughout the $z$-plane cut along the negative real axis, and for fixed $z(\neq 0)$ each is an entire function of $\nu$. When $\nu=\pm n$, $I_\nu(z)$ is an entire function of $z$.

$I_\nu(z)$ $(\mathscr{R}\nu\geq 0)$ is bounded as $z\rightarrow 0$ in any bounded range of arg $z$. $I_\nu(z)$ and $I_{-\nu}(z)$ are linearly independent except when $\nu$ is an integer. $K_\nu(z)$ tends to zero as $|z|\rightarrow\infty$ in the sector $|\arg z|<\frac{1}{2}\pi$, and for all values of $\nu$, $I_\nu(z)$ and $K_\nu(z)$ are linearly independent. $I_\nu(z)$, $K_\nu(z)$ are real and positive when $\nu>-1$ and $z>0$.

### Relations Between Solutions

**9.6.2** $$K_\nu(z)=\tfrac{1}{2}\pi\frac{I_{-\nu}(z)-I_\nu(z)}{\sin(\nu\pi)}$$

The right of this equation is replaced by its limiting value if $\nu$ is an integer or zero.

**9.6.3**

$$I_\nu(z)=e^{-\frac{1}{2}\nu\pi i}J_\nu(ze^{\frac{1}{2}\pi i})\qquad(-\pi<\arg z\leq\tfrac{1}{2}\pi)$$

$$I_\nu(z)=e^{3\nu\pi i/2}J_\nu(ze^{-3\pi i/2})\qquad(\tfrac{1}{2}\pi<\arg z\leq\pi)$$

**9.6.4**

$$K_\nu(z)=\tfrac{1}{2}\pi ie^{\frac{1}{2}\nu\pi i}H_\nu^{(1)}(ze^{\frac{1}{2}\pi i})\qquad(-\pi<\arg z\leq\tfrac{1}{2}\pi)$$

$$K_\nu(z)=-\tfrac{1}{2}\pi ie^{-\frac{1}{2}\nu\pi i}H_\nu^{(2)}(ze^{-\frac{1}{2}\pi i})(-\tfrac{1}{2}\pi<\arg z\leq\pi)$$

**9.6.5**

$$Y_\nu(ze^{\frac{1}{2}\pi i})=e^{\frac{1}{2}(\nu+1)\pi i}I_\nu(z)-(2/\pi)e^{-\frac{1}{2}\nu\pi i}K_\nu(z)$$
$$(-\pi<\arg z\leq\tfrac{1}{2}\pi)$$

**9.6.6** $$I_{-n}(z)=I_n(z),\ K_{-\nu}(z)=K_\nu(z)$$

Most of the properties of modified Bessel functions can be deduced immediately from those of ordinary Bessel functions by application of these relations.

### Limiting Forms for Small Arguments

**9.6.9** $$K_\nu(z)\sim\tfrac{1}{2}\Gamma(\nu)(\tfrac{1}{2}z)^{-\nu}\qquad(\mathscr{R}\nu>0)$$

### Ascending Series

$$K_n(z)=\tfrac{1}{2}(\tfrac{1}{2}z)^{-n}\sum_{k=0}^{n-1}\frac{(n-k-1)!}{k!}(-\tfrac{1}{4}z^2)^k$$

where $\psi(n)$ is given by **6.3.2.**

**9.6.12** $$I_0(z)=1+\frac{\tfrac{1}{4}z^2}{(1!)^2}+\frac{(\tfrac{1}{4}z^2)^2}{(2!)^2}+\frac{(\tfrac{1}{4}z^2)^3}{(3!)^2}+\ldots$$

**9.6.13**

$$K_0(z)=-\{\ln(\tfrac{1}{2}z)+\gamma\}I_0(z)+\frac{\tfrac{1}{4}z^2}{(1!)^2}$$
$$+(1+\tfrac{1}{2})\frac{(\tfrac{1}{4}z^2)^2}{(2!)^2}+(1+\tfrac{1}{2}+\tfrac{1}{3})\frac{(\tfrac{1}{4}z^2)^3}{(3!)^2}+\ldots$$

### Wronskians

**9.6.14**

$$W\{I_\nu(z),I_{-\nu}(z)\}=I_\nu(z)I_{-(\nu+1)}(z)-I_{\nu+1}(z)I_{-\nu}(z)$$
$$=-2\sin(\nu\pi)/(\pi z)$$

### Other Differential Equations

The quantity $\lambda^2$ in equations **9.1.49** to **9.1.54** and **9.1.56** can be replaced by $-\lambda^2$ if at the same time the symbol $\mathscr{C}$ in the given solutions is replaced by $\mathscr{Z}$.

**9.6.41**

$$z^2w''+z(1\pm 2z)w'+(\pm z-\nu^2)w=0, \qquad w=e^{\mp z}\mathscr{Z}_\nu(z)$$

Differential equations for products may be obtained from **9.1.57** to **9.1.59** by replacing $z$ by $iz$.

### Derivatives With Respect to Order

**9.6.42**

$$\frac{\partial}{\partial\nu}I_\nu(z)=I_\nu(z)\ln(\tfrac{1}{2}z)-(\tfrac{1}{2}z)^\nu\sum_{k=0}^{\infty}\frac{\psi(\nu+k+1)}{\Gamma(\nu+k+1)}\frac{(\frac{1}{4}z^2)^k}{k!}$$

**9.6.43**

$$\left[\frac{\partial}{\partial\nu}I_\nu(z)\right]_{\nu=0}=-K_0(z), \qquad \left[\frac{\partial}{\partial\nu}K_\nu(z)\right]_{\nu=0}=0$$

### Expressions in Terms of Hypergeometric Functions

**9.6.47**

$$I_\nu(z)=\frac{(\frac{1}{2}z)^\nu}{\Gamma(\nu+1)}\,{}_0F_1(\nu+1;\tfrac{1}{4}z^2)$$
$$=\frac{(\frac{1}{2}z)^\nu e^{-z}}{\Gamma(\nu+1)}M(\nu+\tfrac{1}{2},2\nu+1,2z)=\frac{z^{-\frac{1}{2}}M_{0,\nu}(2z)}{2^{2\nu+\frac{1}{2}}\Gamma(\nu+1)}$$

**9.6.48** $$K_\nu(z)=\left(\frac{\pi}{2z}\right)^{\frac{1}{2}}W_{0,\nu}(2z)$$

(${}_0F_1$ is the generalized hypergeometric function. For $M(a,b,z)$, $M_{0,\nu}(z)$ and $W_{0,\nu}(z)$ see chapter **13**.)

### Connection With Legendre Functions

If $\mu$ and $z$ are fixed, $\mathscr{R}z>0$, and $\nu\rightarrow\infty$ through real positive values

**9.6.49** $$\lim\left\{\nu^\mu P_\nu^{-\mu}\left(\cosh\frac{z}{\nu}\right)\right\}=I_\mu(z)$$

**9.6.50** $$\lim\left\{\nu^{-\mu}e^{-\mu\pi i}Q_\nu^\mu\left(\cosh\frac{z}{\nu}\right)\right\}=K_\mu(z)$$

For the definition of $P_\nu^{-\mu}$ and $Q_\nu^\mu$, see chapter **8**.

### Multiplication Theorems

**9.6.51**

$$\mathscr{Z}_\nu(\lambda z)=\lambda^{\pm\nu}\sum_{k=0}^{\infty}\frac{(\lambda^2-1)^k(\frac{1}{2}z)^k}{k!}\mathscr{Z}_{\nu\pm k}(z) \qquad (|\lambda^2-1|<1)$$

If $\mathscr{Z}=I$ and the upper signs are taken, the restriction on $\lambda$ is unnecessary.

**9.6.52**

$$I_\nu(z)=\sum_{k=0}^{\infty}\frac{z^k}{k!}J_{\nu+k}(z), \qquad J_\nu(z)=\sum_{k=0}^{\infty}(-)^k\frac{z^k}{k!}I_{\nu+k}(z)$$

### Neumann Series for $K_n(z)$

**9.6.53**

$$K_n(z)=(-)^{n-1}\{\ln(\tfrac{1}{2}z)-\psi(n+1)\}I_n(z)$$
$$+\frac{n!(\frac{1}{2}z)^{-n}}{2}\sum_{k=0}^{n-1}(-)^k\frac{(\frac{1}{2}z)^kI_k(z)}{(n-k)k!}$$
$$+(-)^n\sum_{k=1}^{\infty}\frac{(n+2k)I_{n+2k}(z)}{k(n+k)}$$

**9.6.54** $$K_0(z)=-\{\ln(\tfrac{1}{2}z)+\gamma\}I_0(z)+2\sum_{k=1}^{\infty}\frac{I_{2k}(z)}{k}$$

### Zeros

Properties of the zeros of $I_\nu(z)$ and $K_\nu(z)$ may be deduced from those of $J_\nu(z)$ and $H_\nu^{(1)}(z)$ respectively, by application of the transformations **9.6.3** and **9.6.4**.

For example, if $\nu$ is real the zeros of $I_\nu(z)$ are all complex unless $-2k<\nu<-(2k-1)$ for some positive integer $k$, in which event $I_\nu(z)$ has two real zeros.

The approximate distribution of the zeros of $K_n(z)$ in the region $-\frac{3}{2}\pi\leq\arg z\leq\frac{1}{2}\pi$ is obtained on rotating **Figure 9.6** through an angle $-\frac{1}{2}\pi$ so that the cut lies along the positive imaginary axis. The zeros in the region $-\frac{1}{2}\pi\leq\arg z\leq\frac{3}{2}\pi$ are their conjugates. $K_n(z)$ has no zeros in the region $|\arg z|\leq\frac{1}{2}\pi$; this result remains true when $n$ is replaced by any real number $\nu$.

## 9.7. Asymptotic Expansions

### Asymptotic Expansions for Large Arguments

When $\nu$ is fixed, $|z|$ is large and $\mu=4\nu^2$

**9.7.1**

$$I_\nu(z)\sim\frac{e^z}{\sqrt{2\pi z}}\left\{1-\frac{\mu-1}{8z}+\frac{(\mu-1)(\mu-9)}{2!(8z)^2}\right.$$
$$\left.-\frac{(\mu-1)(\mu-9)(\mu-25)}{3!(8z)^3}+\ldots\right\} \qquad (|\arg z|<\tfrac{1}{2}\pi)$$

**9.7.2**

$$K_\nu(z)\sim\sqrt{\frac{\pi}{2z}}\,e^{-z}\left\{1+\frac{\mu-1}{8z}+\frac{(\mu-1)(\mu-9)}{2!(8z)^2}+\frac{(\mu-1)(\mu-9)(\mu-25)}{3!(8z)^3}+\ldots\right\}\qquad(|\arg z|<\tfrac{3}{2}\pi)$$

**9.7.3**

$$I'_\nu(z)\sim\frac{e^z}{\sqrt{2\pi z}}\left\{1-\frac{\mu+3}{8z}+\frac{(\mu-1)(\mu+15)}{2!(8z)^2}-\frac{(\mu-1)(\mu-9)(\mu+35)}{3!(8z)^3}+\ldots\right\}\qquad(|\arg z|<\tfrac{1}{2}\pi)$$

**9.7.4**

$$K'_\nu(z)\sim-\sqrt{\frac{\pi}{2z}}e^{-z}\left\{1+\frac{\mu+3}{8z}+\frac{(\mu-1)(\mu+15)}{2!(8z)^2}+\frac{(\mu-1)(\mu-9)(\mu+35)}{3!(8z)^3}+\ldots\right\}\qquad(|\arg z|<\tfrac{3}{2}\pi)$$

The general terms in the last two expansions can be written down by inspection of **9.2.15** and **9.2.16.**

If $\nu$ is real and non-negative and $z$ is positive the remainder after $k$ terms in the expansion **9.7.2** does not exceed the $(k+1)$th term in absolute value and is of the same sign, provided that $k\geq\nu-\frac{1}{2}$.

**9.7.5**

$$I_\nu(z)K_\nu(z)\sim\frac{1}{2z}\left\{1-\frac{1}{2}\frac{\mu-1}{(2z)^2}+\frac{1\cdot3}{2\cdot4}\frac{(\mu-1)(\mu-9)}{(2z)^4}-\ldots\right\}\qquad(|\arg z|<\tfrac{1}{2}\pi)$$

**9.7.6**

$$I'_\nu(z)K'_\nu(z)\sim-\frac{1}{2z}\left\{1+\frac{1}{2}\frac{\mu-3}{(2z)^2}-\frac{1\cdot1}{2\cdot4}\frac{(\mu-1)(\mu-45)}{(2z)^4}+\ldots\right\}\qquad(|\arg z|<\tfrac{1}{2}\pi)$$

The general terms can be written down by inspection of **9.2.28** and **9.2.30.**

#### Uniform Asymptotic Expansions for Large Orders

**9.7.7** $$I_\nu(\nu z)\sim\frac{1}{\sqrt{2\pi\nu}}\frac{e^{\nu\eta}}{(1+z^2)^{1/4}}\left\{1+\sum_{k=1}^{\infty}\frac{u_k(t)}{\nu^k}\right\}$$

**9.7.8**

$$K_\nu(\nu z)\sim\sqrt{\frac{\pi}{2\nu}}\frac{e^{-\nu\eta}}{(1+z^2)^{1/4}}\left\{1+\sum_{k=1}^{\infty}(-)^k\frac{u_k(t)}{\nu^k}\right\}$$

**9.7.9** $$I'_\nu(\nu z)\sim\frac{1}{\sqrt{2\pi\nu}}\frac{(1+z^2)^{1/4}}{z}e^{\nu\eta}\left\{1+\sum_{k=1}^{\infty}\frac{v_k(t)}{\nu^k}\right\}$$

**9.7.10**

$$K'_\nu(\nu z)\sim-\sqrt{\frac{\pi}{2\nu}}\frac{(1+z^2)^{1/4}}{z}e^{-\nu\eta}\left\{1+\sum_{k=1}^{\infty}(-)^k\frac{v_k(t)}{\nu^k}\right\}$$

When $\nu\rightarrow+\infty$, these expansions hold uniformly with respect to $z$ in the sector $|\arg z|\leq\frac{1}{2}\pi-\epsilon$, where $\epsilon$ is an arbitrary positive number. Here

**9.7.11** $$t=1/\sqrt{1+z^2},\qquad\eta=\sqrt{1+z^2}+\ln\frac{z}{1+\sqrt{1+z^2}}$$

and $u_k(t)$, $v_k(t)$ are given by **9.3.9, 9.3.10, 9.3.13** and **9.3.14**. See [9.38] for tables of $\eta$, $u_k(t)$, $v_k(t)$, and also for bounds on the remainder terms in **9.7.7** to **9.7.10.**

### Functions of Negative Argument

In general Kelvin functions have a branch point at $x=0$ and individual functions with arguments $xe^{\pm\pi i}$ are complex. The branch point is absent however in the case of $\operatorname{ber}_\nu$ and $\operatorname{bei}_\nu$ when $\nu$ is an integer, and

## 9.10. Asymptotic Expansions

### Asymptotic Expansions for Large Arguments

When $\nu$ is fixed and $x$ is large

**9.10.1**

$$\mathrm{ber}_\nu\,x=\frac{e^{x/\sqrt{2}}}{\sqrt{2\pi x}}\{f_\nu(x)\cos\alpha+g_\nu(x)\sin\alpha\}$$
$$-\frac{1}{\pi}\,\{\sin(2\nu\pi)\,\mathrm{ker}_\nu\,x+\cos(2\nu\pi)\,\mathrm{kei}_\nu\,x\}$$

**9.10.2**

$$\mathrm{bei}_\nu\,x=\frac{e^{x/\sqrt{2}}}{\sqrt{2\pi x}}\{f_\nu(x)\sin\alpha-g_\nu(x)\cos\alpha\}$$
$$+\frac{1}{\pi}\,\{\cos(2\nu\pi)\,\mathrm{ker}_\nu\,x-\sin(2\nu\pi)\,\mathrm{kei}_\nu\,x\}$$

**9.10.3**

$$\mathrm{ker}_\nu\,x=\sqrt{\pi/(2x)}\,e^{-x/\sqrt{2}}\{f_\nu(-x)\cos\beta-g_\nu(-x)\sin\beta\}$$

**9.10.4**

$$\mathrm{kei}_\nu\,x=\sqrt{\pi/(2x)}\,e^{-x/\sqrt{2}}\{-f_\nu(-x)\sin\beta-g_\nu(-x)\cos\beta\}$$

where

**9.10.5**

$$\alpha=(x/\sqrt{2})+(\tfrac{1}{2}\nu-\tfrac{1}{8})\pi,\qquad \beta=(x/\sqrt{2})+(\tfrac{1}{2}\nu+\tfrac{1}{8})\pi=\alpha+\tfrac{1}{4}\pi$$

and, with $4\nu^2$ denoted by $\mu$,

**9.10.6**

$$f_\nu(\pm x)$$
$$\sim 1+\sum_{k=1}^{\infty}(\mp)^k\frac{(\mu-1)(\mu-9)\ldots\{\mu-(2k-1)^2\}}{k!(8x)^k}\cos\left(\frac{k\pi}{4}\right)$$

---

[5] From British Association for the Advancement of Science, Annual Report (J. R. Airey), 254 (1927) with permission. This reference also gives 5-decimal values of the next five zeros of each function.

**9.10.7**

$$g_\nu(\pm x)$$

$$\sim\sum_{k=1}^{\infty}(\mp)^k\frac{(\mu-1)(\mu-9)\ldots\{\mu-(2k-1)^2\}}{k!(8x)^k}\sin\left(\frac{k\pi}{4}\right)$$

The terms[6] in $\mathrm{ker}_\nu x$ and $\mathrm{kei}_\nu x$ in equations **9.10.1** and **9.10.2** are asymptotically negligible compared with the other terms, but their inclusion in numerical calculations yields improved accuracy.

The corresponding series for $\mathrm{ber}'_\nu x$, $\mathrm{bei}'_\nu x$, $\mathrm{ker}'_\nu x$ and $\mathrm{kei}'_\nu x$ can be derived from **9.2.11** and **9.2.13** with $z=xe^{3\pi i/4}$; the extra terms in the expansions of $\mathrm{ber}'_\nu x$ and $\mathrm{bei}'_\nu x$ are respectively

$$-(1/\pi)\{\sin(2\nu\pi)\mathrm{ker}'_\nu x+\cos(2\nu\pi)\mathrm{kei}'_\nu x\}$$

and

$$(1/\pi)\{\cos(2\nu\pi)\mathrm{ker}'_\nu x-\sin(2\nu\pi)\mathrm{kei}'_\nu x\}.$$

### Asymptotic Expansions of Large Zeros

Let

**9.10.35**

$$f(\delta)=\frac{\mu-1}{16\delta}+\frac{\mu-1}{32\delta^2}+\frac{(\mu-1)(5\mu+19)}{1536\delta^3}+\frac{3(\mu-1)^2}{512\delta^4}+\cdots$$

Zeros of $\mathrm{ber}_\nu\,x\sim\sqrt{2}\{\delta-f(\delta)\}$, $\quad\delta=(s-\frac{1}{2}\nu-\frac{3}{8})\pi$

Zeros of $\mathrm{bei}_\nu\,x\sim\sqrt{2}\{\delta-f(\delta)\}$, $\quad\delta=(s-\frac{1}{2}\nu+\frac{1}{8})\pi$

Zeros of $\mathrm{ker}_\nu\,x\sim\sqrt{2}\{\delta+f(-\delta)\}$, $\quad\delta=(s-\frac{1}{2}\nu-\frac{5}{8})\pi$

Zeros of $\mathrm{kei}_\nu\,x\sim\sqrt{2}\{\delta+f(-\delta)\}$, $\quad\delta=(s-\frac{1}{2}\nu-\frac{1}{8})\pi$

## Numerical Methods

### 9.12. Use and Extension of the Tables

**Example 1.** To evaluate $J_n(1.55)$, $n=0, 1, 2, \ldots$, each to 5 decimals.

The recurrence relation

$$J_{n-1}(x) + J_{n+1}(x) = (2n/x)J_n(x)$$

can be used to compute $J_0(x)$, $J_1(x)$, $J_2(x)$, . . ., successively provided that $n < x$, otherwise severe accumulation of rounding errors will occur. Since, however, $J_n(x)$ is a decreasing function of $n$ when $n > x$, recurrence can always be carried out in the direction of decreasing $n$.

Inspection of **Table 9.2** shows that $J_n(1.55)$ vanishes to 5 decimals when $n > 7$. Taking arbitrary values zero for $J_9$ and unity for $J_8$, we compute by recurrence the entries in the second column of the following table, rounding off to the nearest integer at each step.

| *n* | *Trial values* | *$J_n(1.55)$* |
|---|---|---|
| 9 | 0 | .00000 |
| 8 | 1 | .00000 |
| 7 | 10 | .00003 |
| 6 | 89 | .00028 |
| 5 | 679 | .00211 |
| 4 | 4292 | .01331 |
| 3 | 21473 | .06661 |
| 2 | 78829 | .24453 |
| 1 | 181957 | .56442 |
| 0 | 155954 | .48376 |

We normalize the results by use of the equation **9.1.46**, namely

$$J_0(x) + 2J_2(x) + 2J_4(x) + \ldots = 1$$

This yields the normalization factor

$$1/322376 = .00000\ 31019\ 7$$

and multiplying the trial values by this factor we obtain the required results, given in the third column. As a check we may verify the value of $J_0(1.55)$ by interpolation in **Table 9.1.**

**Remarks.** (i) In this example it was possible to estimate immediately the value of $n=N$, say, at which to begin the recurrence. This may not always be the case and an arbitrary value of $N$ may have to be taken. The number of correct significant figures in the final values is the same as the number of digits in the respective trial values. If the chosen $N$ is too small the trial values will have too few digits and insufficient accuracy is obtained in the results. The calculation must then be repeated taking a higher value. On the other hand if $N$ were too large unnecessary effort would be expended. This could be offset to some extent by discarding significant figures in the trial values which are in excess of the number of decimals required in $J_n$.

(ii) If we had required, say, $J_0(1.55)$, $J_1(1.55)$, . . ., $J_{10}(1.55)$, each to 5 significant figures, we would have found the values of $J_{10}(1.55)$ and $J_{11}(1.55)$ to 5 significant figures by interpolation in **Table 9.3** and then computed by recurrence $J_9$, $J_8$, . . ., $J_0$, no normalization being required. Alternatively, we could begin the recurrence at a higher value of $N$ and retain only 5 significant figures in the trial values for $n\leq 10$.

(iii) Exactly similar methods can be used to compute the modified Bessel function $I_n(x)$ by means of the relations **9.6.26** and **9.6.36.** If $x$ is large, however, considerable cancellation will take place in using the latter equation, and it is preferable to normalize by means of **9.6.37.**

**Example 2.** To evaluate $Y_n(1.55)$, $n=0, 1, 2, . . ., 10$, each to 5 significant figures.

The recurrence relation

$$Y_{n-1}(x)+Y_{n+1}(x)=(2n/x)Y_n(x)$$

can be used to compute $Y_n(x)$ in the direction of increasing $n$ both for $n<x$ and $n>x$, because in the latter event $Y_n(x)$ is a numerically increasing function of $n$.

We therefore compute $Y_0(1.55)$ and $Y_1(1.55)$ by interpolation in **Table 9.1,** generate $Y_2(1.55)$, $Y_3(1.55)$, . . ., $Y_{10}(1.55)$ by recurrence and check $Y_{10}(1.55)$ by interpolation in **Table 9.3.**

| $n$ | $Y_n(1.55)$ | $n$ | $Y_n(1.55)$ |
|---|---|---|---|
| 0 | $+0.40225$ | 6 | $-1.9917\times 10^2$ |
| 1 | $-0.37970$ | 7 | $-1.5100\times 10^3$ |
| 2 | $-0.89218$ | 8 | $-1.3440\times 10^4$ |
| 3 | $-1.9227$ | 9 | $-1.3722\times 10^5$ |
| 4 | $-6.5505$ | 10 | $-1.5801\times 10^6$ |
| 5 | $-31.886$ | | |

**Remarks.** (i) An alternative way of computing $Y_0(x)$, should $J_0(x)$, $J_2(x)$, $J_4(x)$, . . ., be available (see **Example 1**), is to use formula **9.1.89.** The other starting value for the recurrence, $Y_1(x)$, can then be found from the Wronskian relation $J_1(x)Y_0(x)-J_0(x)Y_1(x)=2/(\pi x)$. This is a convenient procedure for use with an automatic computer.

(ii) Similar methods can be used to compute the modified Bessel function $K_n(x)$ by means of the recurrence relation **9.6.26** and the relation **9.6.54,** except that if $x$ is large severe cancellation will occur in the use of **9.6.54** and other methods for evaluating $K_0(x)$ may be preferable, for example, use of the asymptotic expansion **9.7.2** or the polynomial approximation **9.8.6.**

**Example 3.** To evaluate $J_0(.36)$ and $Y_0(.36)$ each to 5 decimals, using the multiplication theorem.

From **9.1.74** we have

$$\mathscr{C}_0(\lambda z)=\sum_{k=0}^{\infty}a_k\mathscr{C}_k(z),\text{ where } a_k=\frac{(-)^k(\lambda^2-1)^k(\tfrac{1}{2}z)^k}{k!}.$$

We take $z=.4$. Then $\lambda=.9$, $(\lambda^2-1)(\tfrac{1}{2}z)=-.038$, and extracting the necessary values of $J_k(.4)$ and $Y_k(.4)$ from **Tables 9.1** and **9.2,** we compute the required results as follows:

| $k$ | $a_k$ | $a_kJ_k(.4)$ | $a_kY_k(.4)$ |
|---|---|---|---|
| 0 | $+1.0$ | $+.96040$ | $-.60602$ |
| 1 | $+0.038$ | $+.00745$ | $-.06767$ |
| 2 | $+0.7220\times 10^{-3}$ | $+.00001$ | $-.00599$ |
| 3 | $+0.914\times 10^{-5}$ | | $-.00074$ |
| 4 | $+0.87\times 10^{-7}$ | | $-.00011$ |
| 5 | $+0.7\times 10^{-9}$ | | $-.00002$ |
| | | $J_0(.36)=+.96786$ | $Y_0(.36)=-.68055$ |

**Remark.** This procedure is equivalent to interpolating by means of the Taylor series

$$\mathscr{C}_0(z+h)=\sum_{k=0}^{\infty}\frac{h^k}{k!}\mathscr{C}_0^{(k)}(z)$$

at $z=.4$, and expressing the derivatives $\mathscr{C}_0^{(k)}(z)$ in terms of $\mathscr{C}_k(z)$ by means of the recurrence relations and differential equation for the Bessel functions.

**Example 4.** To evaluate $J_\nu(x)$, $J'_\nu(x)$, $Y_\nu(x)$ and $Y'_\nu(x)$ for $\nu=50$, $x=75$, each to 6 decimals.

We use the asymptotic expansions **9.3.35, 9.3.36, 9.3.43,** and **9.3.44.** Here $z=x/\nu=3/2$. From **9.3.39** we find

$$\frac{2}{3}(-\zeta)^{3/2}=\frac{1}{2}\sqrt{5}-\text{arccos}\,\frac{2}{3}=+.2769653.$$

Hence

$$\zeta=-.5567724 \text{ and } \left(\frac{4\zeta}{1-z^2}\right)^{1/4}=+1.155332.$$

Next,

$$\nu^{1/3}=3.684031, \qquad \nu^{2/3}\zeta=-7.556562.$$

Interpolating in **Table 10.11**, we find that

$$\mathrm{Ai}(\nu^{2/3}\zeta)=+.299953, \qquad \mathrm{Ai}'(\nu^{2/3}\zeta)=+.451441,$$

$$\mathrm{Bi}(\nu^{2/3}\zeta)=-.160565, \qquad \mathrm{Bi}'(\nu^{2/3}\zeta)=+.819542.$$

As a check on the interpolation, we may verify that $\mathrm{Ai}\,\mathrm{Bi}'-\mathrm{Ai}'\mathrm{Bi}=1/\pi$.

Interpolating in the table following **9.3.46** we obtain

$$b_0(\zeta)=+.0136, \qquad c_0(\zeta)=+.1442.$$

The contributions of the terms involving $a_1(\zeta)$ and $d_1(\zeta)$ are negligible, and substituting in the asymptotic expansions we find that

$$J_{50}(75)=+1.155332(50^{-1/3}\times.299953 +50^{-5/3}\times.451441\times.0136)=+.094077,$$

$$J'_{50}(75)=-(4/3)(1.155332)^{-1}(50^{-4/3}\times.299953 \times.1442+50^{-2/3}\times.451441)=-.038658,$$

$$Y_{50}(75)=-1.155332(-50^{-1/3}\times.160565 +50^{-5/3}\times.819542\times.0136)=+.050335,$$

$$Y'_{50}(75)=+(4/3)(1.155332)^{-1}(-50^{-4/3}\times.160565 \times.1442+50^{-2/3}\times.819542)=+.069543.$$

As a check we may verify that

$$JY'-J'Y=2/(75\pi).$$

**Remarks.** This example may also be computed using the Debye expansions **9.3.15, 9.3.16, 9.3.19,** and **9.3.20.** Four terms of each of these series are required, compared with two in the computations above. The closer the argument-order ratio is to unity, the less effective the Debye expansions become. In the neighborhood of unity the expansions **9.3.23, 9.3.24, 9.3.27,** and **9.3.28** will furnish results of moderate accuracy; for high-accuracy work the uniform expansions should again be used.

**Example 5.** To evaluate the 5th positive zero of $J_{10}(x)$ and the corresponding value of $J'_{10}(x)$, each to 5 decimals.

We use the asymptotic expansions **9.5.22** and **9.5.23** setting $\nu=10$, $s=5$. From **Table 10.11** we find

$$a_5=-7.944134, \qquad \mathrm{Ai}'(a_5)=+.947336.$$

Hence

$$\zeta=10^{-2/3}a_5=.21544347a_5=-1.7115118.$$

Interpolating in the table following **9.5.26** we obtain

$$z(\zeta)=+2.888631, \qquad h(\zeta)=+.98259,$$

$$f_1(\zeta)=+.0107, \qquad F_1(\zeta)=-.001.$$

The bounds given at the foot of the table show that the contributions of higher terms to the asymptotic series are negligible. Hence

$$j_{10,5}=28.88631+.00107+\ldots=28.88738,$$

$$J'_{10}(j_{10,5})=-\frac{2}{10^{2/3}}\,\frac{.947336}{2.888631\times.98259} \times(1-.00001+\ldots)=-.14381.$$

**Example 6.** To evaluate the first root of $J_0(x)Y_0(\lambda x)-Y_0(x)J_0(\lambda x)=0$ for $\lambda=\frac{3}{2}$ to 4 significant figures.

Let $\alpha_\lambda^{(1)}$ denote the root. Direct interpolation in **Table 9.7** is impracticable owing to the divergence of the differences. Inspection of **9.5.28** suggests that a smoother function is $(\lambda-1)\alpha_\lambda^{(1)}$. Using **Table 9.7** we compute the following values

| $1/\lambda$ | $(\lambda-1)\alpha_\lambda^{(1)}$ | $\delta$ | $\delta^2$ |
|---|---|---|---|
| 0.4 | 3.110 | | |
| | | +21 | |
| 0.6 | 3.131 | | −12 |
| | | +9 | |
| 0.8 | 3.140 | | −7 |
| | | +2 | |
| 1.0 | 3.142($\pi$) | | |

Interpolating for $1/\lambda=.667$, we obtain $(\lambda-1)\alpha_\lambda^{(1)}=3.134$ and thence the required root $\alpha_{1.5}^{(1)}=6.268$.

**Example 7.** To evaluate $\mathrm{ber}_n\,1.55$, $\mathrm{bei}_n\,1.55$, $n=0, 1, 2, \ldots$, each to 5 decimals.

We use the recurrence relation

$$J_{n-1}(xe^{3\pi i/4})+J_{n+1}(xe^{3\pi i/4}) =-\frac{n\sqrt{2}}{x}(1+i)J_n(xe^{3\pi i/4}),$$

taking arbitrary values zero for $J_9(xe^{3\pi i/4})$ and $1+0i$ for $J_8(xe^{3\pi i/4})$ (see **Example 1**).

| $n$ | Real trial values | Imag. trial values | $\mathrm{ber}_n x$ | $\mathrm{bei}_n x$ |
|---|---|---|---|---|
| 9 | 0 | 0 | .00000 | .00000 |
| 8 | +1 | 0 | .00000 | .00000 |
| 7 | −7 | −7 | −.00002 | −.00003 |
| 6 | −1 | +89 | −.00003 | +.00030 |
| 5 | +500 | −475 | +.00181 | −.00148 |
| 4 | −4447 | −203 | −.01494 | −.00180 |
| 3 | +14989 | +17446 | +.04614 | +.06258 |
| 2 | +11172 | −88578 | +.05994 | −.29580 |
| 1 | −197012 | +123804 | −.69531 | +.36781 |
| 0 | +281539 | +155373 | +.91004 | +.59461 |
| Σ | +106734 | +207449 | +.30763 | +.72619 |

The values of $\mathrm{ber}_n x$ and $\mathrm{bei}_n x$ are computed by multiplication of the trial values by the normalizing factor

$$1/(294989-22011i)=(.337119+.025155i)\times 10^{-5},$$

obtained from the relation

$$J_0(xe^{3\pi i/4})+2J_2(xe^{3\pi i/4})+2J_4(xe^{3\pi i/4})+\ldots=1.$$

Adequate checks are furnished by interpolating in **Table 9.12** for ber 1.55 and bei 1.55, and the use of a simple sum check on the normalization.

Should $\mathrm{ker}_n x$ and $\mathrm{kei}_n x$ be required they can be computed by forward recurrence using formulas **9.9.14**, taking the required starting values for $n=0$ and 1 from **Table 9.12** (see **Example 2**). If an independent check on the recurrence is required the asymptotic expansion **9.10.38** can be used.

For interpolating near $x^{-1}=0$ note that if $f_n(x^{-1})=x^{\frac{1}{2}}e^{-x}I_n(x)$ then $f_n(-x^{-1})=\pi^{-1}x^{\frac{1}{2}}e^{x}K_n(x)$.

$<x>$ =nearest integer to $x$.

# 10. Bessel Functions of Fractional Order

## Mathematical Properties

### 10.1. Spherical Bessel Functions

#### Definitions

**Differential Equation**

**10.1.1**

$$z^2w''+2zw'+[z^2-n(n+1)]w=0 \qquad (n=0, \pm 1, \pm 2, \ldots)$$

Particular solutions are the *Spherical Bessel functions of the first kind*

$$j_n(z)=\sqrt{\tfrac{1}{2}\pi/z}\,J_{n+\frac12}(z),$$

the *Spherical Bessel functions of the second kind*

$$y_n(z)=\sqrt{\tfrac{1}{2}\pi/z}\,Y_{n+\frac12}(z),$$

and the *Spherical Bessel functions of the third kind*

$$h_n^{(1)}(z)=j_n(z)+iy_n(z)=\sqrt{\tfrac{1}{2}\pi/z}\,H^{(1)}_{n+\frac12}(z),$$

$$h_n^{(2)}(z)=j_n(z)-iy_n(z)=\sqrt{\tfrac{1}{2}\pi/z}\,H^{(2)}_{n+\frac12}(z).$$

The pairs $j_n(z)$, $y_n(z)$ and $h_n^{(1)}(z)$, $h_n^{(2)}(z)$ are linearly independent solutions for every $n$. For general properties see the remarks after **9.1.1.**

**Ascending Series (See 9.1.2, 9.1.10)**

**10.1.2**

$$j_n(z)=\frac{z^n}{1\cdot3\cdot5\ldots(2n+1)}\left\{1-\frac{\frac12 z^2}{1!(2n+3)}+\frac{(\frac12 z^2)^2}{2!(2n+3)(2n+5)}-\ldots\right\}$$

**10.1.3**

$$y_n(z)=-\frac{1\cdot3\cdot5\ldots(2n-1)}{z^{n+1}}\left\{1-\frac{\frac12 z^2}{1!(1-2n)}+\frac{(\frac12 z^2)^2}{2!(1-2n)(3-2n)}-\ldots\right\}$$

$$(n=0, 1, 2, \ldots)$$

**Limiting Values as $z\rightarrow 0$**

**10.1.4** $$z^{-n}j_n(z)\rightarrow\frac{1}{1\cdot3\cdot5\ldots(2n+1)}$$

**10.1.5**

$$z^{n+1}y_n(z)\rightarrow -1\cdot3\cdot5\ldots(2n-1) \qquad (n=0, 1, 2, \ldots)$$

**Wronskians**

**10.1.6** $$W\{j_n(z), y_n(z)\}=z^{-2}$$

**10.1.7**

$$W\{h_n^{(1)}(z), h_n^{(2)}(z)\}=-2iz^{-2} \qquad (n=0, 1, 2, \ldots)$$

## Zeros and Their Asymptotic Expansions

The zeros of $j_n(x)$ and $y_n(x)$ are the same as the zeros of $J_{n+\frac{1}{2}}(x)$ and $Y_{n+\frac{1}{2}}(x)$ and the formulas for $j_{\nu,s}$ and $y_{\nu,s}$ given in **9.5** are applicable with $\nu=n+\frac{1}{2}$. There are, however, no simple relations connecting the zeros of the derivatives. Accordingly, we now give formulas for $a'_{n,s}$, $b'_{n,s}$, the $s$-th positive zero of $j'_n(z)$, $y'_n(z)$, respectively; $z=0$ is counted as the first zero of $j'_0(z)$.

(Tables of $a'_{n,s}$, $b'_{n,s}$, $j_n(a'_{n,s})$, $y_n(b'_{n,s})$ are given in [10.31].)

### Elementary Relations

$$f_n(z)=j_n(z)\cos\pi t+y_n(z)\sin\pi t$$

($t$ a real parameter, $0\leq t\leq 1$)

If $\tau_n$ is a zero of $f'_n(z)$ then

**10.1.55** $f_n(\tau_n)=[\tau_n/(n+1)]f_{n-1}(\tau_n)$
(See **10.1.21.**)

**10.1.56** $=(\tau_n/n)f_{n+1}(\tau_n)$
(See **10.1.22.**)

**10.1.57** $$=\left\{\frac{1}{\pi}[\tau_n^2-n(n+1)]\frac{d\tau_n}{d\tau}\right\}^{-\frac{1}{2}}$$

### Complex Zeros of $h_n^{(1)}(z)$, $h_n^{(1)\prime}(z)$

$h_n^{(1)}(z)$ and $h_n^{(1)}(ze^{2m\pi i})$, $m$ any integer, have the same zeros.

$h_n^{(1)}(z)$ has $n$ zeros, symmetrically distributed with respect to the imaginary axis and lying approximately on the finite arc joining $z=-n$ and $z=n$ shown in **Figure 9.6.** If $n$ is odd, one zero lies on the imaginary axis.

$h_n^{(1)\prime}(z)$ has $n+1$ zeros lying approximately on the same curve. If $n$ is even, one zero lies on the imaginary axis.

### Formal and Asymptotic Solutions of Ordinary Differential Equations of Second Order With Turning Points

An equation

**10.4.106** $$W''+a(z,\lambda)W'+b(z,\lambda)W=0$$

in which $\lambda$ is a real or complex parameter and, for fixed $\lambda$, $a(z,\lambda)$ is analytic in $z$ and $b(z,\lambda)$ is continuous in $z$ in some region of the $z$-plane, may be reduced by the transformation

**10.4.107** $$W(z)=w(z)\exp\left(-\frac{1}{2}\int^z a(t,\lambda)dt\right)$$

to the equation

**10.4.108**
$$w''+\varphi(z,\lambda)w=0$$

$$\varphi(z,\lambda)=b(z,\lambda)-\frac{1}{4}a^2(z,\lambda)-\frac{1}{2}\frac{d}{dz}a(z,\lambda).$$

---

*See page II.

If $\varphi(z,\lambda)$ can be written in the form

**10.4.109** $$\varphi(z,\lambda)=\lambda^2 p(z)+q(z,\lambda)$$

where $q(z,\lambda)$ is bounded in a region $R$ of the $z$-plane, then the zeros of $p(z)$ in $R$ are said to be turning points of the equation **10.4.108.**

### The Special Case $w''+[\lambda^2 z+q(z,\lambda)]w=0$

Let $\lambda=|\lambda|e^{i\omega}$ vary over a sectorial domain $S$: $|\lambda|\geq\lambda_0(>0)$, $\omega_1\leq\omega\leq\omega_2$, and suppose that $q(z,\lambda)$ is continuous in $z$ for $|z|<r$ and $\lambda$ in $S$, and $q(z,\lambda)\sim\sum_0^{\infty} q_n(z)\lambda^{-n}$ as $\lambda\to\infty$ in $S$.

### Formal Series Solution

**10.4.110**

$$w(z)=u(z)\sum_0^{\infty}\varphi_n(z)\lambda^{-n}+\lambda^{-1}u'(z)\sum_0^{\infty}\psi_n(z)\lambda^{-n}$$

$$u''+\lambda^2 zu=0$$

$$\varphi_0(z)=c_0,\qquad \psi_0(z)=z^{-\frac{1}{2}}c_1,\qquad c_0,\ c_1 \text{ constants}$$

$$\varphi_{n+1}(z)=-\frac{1}{2}\psi_n'(z)-\frac{1}{2}\int_0^z\sum_0^n q_{n-k}(t)\psi_k(t)dt$$

$$\psi_n(z)=\frac{1}{2}z^{-\frac{1}{2}}\int_0^z t^{-\frac{1}{2}}\left[\varphi_n''(t)+\sum_0^n q_{n-k}(t)\varphi_k(t)\right]dt$$

$$(n=0,1,2,\ldots)$$

### Uniform Asymptotic Expansions of Solutions

For $z$ real, i.e. for the equation

**10.4.111** $$y''+[\lambda^2 x+q(x,\lambda)]y=0$$

where $x$ varies in a bounded interval $a\leq x\leq b$ that includes the origin and where, for each fixed $\lambda$ in $S$, $q(x,\lambda)$ is continuous in $x$ for $a\leq x\leq b$, the following asymptotic representations hold.

(i) If $\lambda$ is real and positive, there are solutions $y_0(x)$, $y_1(x)$ such that, uniformly in $x$ on $a\leq x\leq 0$,

**10.4.112**

$$y_0(x)=\text{Ai}\,(-\lambda^{2/3}x)[1+O(\lambda^{-1})]\qquad(\lambda\to\infty)$$

$$y_1(x)=\text{Bi}\,(-\lambda^{2/3}x)[1+O(\lambda^{-1})]$$

and, uniformly in $x$ on $0\leq x\leq b$

**10.4.113**

$$y_0(x)=\text{Ai}\,(-\lambda^{2/3}x)[1+O(\lambda^{-1})]+\text{Bi}\,(-\lambda^{2/3}x)O(\lambda^{-1}),$$

$$y_1(x)=\text{Bi}\,(-\lambda^{2/3}x)[1+O(\lambda^{-1})]+\text{Ai}\,(-\lambda^{2/3}x)O(\lambda^{-1})$$

$$(\lambda\to\infty)$$

(ii) If $\mathscr{R}\lambda\geq 0$, $\mathscr{I}\lambda\neq 0$, there are solutions $y_0(x)$, $y_1(x)$ such that, uniformly in $x$ on $a\leq x\leq b$,

**10.4.114**

$$y_0(x)=\text{Ai}\,(-\lambda^{2/3}x)[1+O(\lambda^{-1})]$$

$$y_1(x)=\text{Bi}\,(-\lambda^{2/3}x)[1+O(\lambda^{-1})]\qquad(|\lambda|\to\infty)$$

For further representations and details, we refer to [10.4].

When $z$ is complex (bounded or unbounded), conditions under which the formal series **10.4.110** yields a uniform asymptotic expansion of a solution are given in [10.12] if $q(z,\lambda)$ is independent of $\lambda$ and $|\lambda|\to\infty$ with fixed $\omega$, and in [10.14] if $\lambda$ lies in any region of the complex plane. Further references are [10.2; 10.9; 10.10].

### The General Case $w''+[\lambda^2 p(z)+q(z,\lambda)]w=0$

Let $\lambda=|\lambda|e^{i\omega}$ where $|\lambda|\geq\lambda_0(>0)$ and $-\pi\leq\omega\leq\pi$; suppose that $p(z)$ is analytic in a region $R$ and has a zero $z=z_0$ in $R$, and that, for fixed $\lambda$, $q(z,\lambda)$ is analytic in $z$ for $z$ in $R$. The transformation $\xi=\xi(z)$, $v=[p(z)/\xi]^{1/4}w(z)$, where $\xi$ is defined as the (unique) solution of the equation

**10.4.115** $$\xi\left(\frac{d\xi}{dz}\right)^2=p(z),$$

yields the special case

**10.4.116** $$\frac{d^2v}{d\xi^2}+[\lambda^2\xi+f(\xi,\lambda)]v=0,\qquad *$$

$$f(\xi,\lambda)=\left(\frac{d\xi}{dz}\right)^{-2}q(z,\lambda)-\left(\frac{d\xi}{dz}\right)^{-\frac{1}{2}}\frac{d^2}{d\xi^2}\left[\left(\frac{d\xi}{dz}\right)^{\frac{1}{2}}\right].$$

*Example:*

Consider the equation

**10.4.117** $$y''+[\lambda^2-(\lambda^2-\tfrac{1}{4})\,x^{-2}]y=0$$

for which the points $x=0$, $\infty$ are singular points and $x=1$ is a turning point. It has the functions $x^{\frac{1}{2}}J_\lambda(\lambda x)$, $x^{\frac{1}{2}}Y_\lambda(\lambda x)$ as particular solutions (see **9.1.49**).

The equation **10.4.115** becomes

$$\xi\left(\frac{d\xi}{dx}\right)^2=\frac{x^2-1}{x^2}$$

whence

$$\tfrac{2}{3}(-\xi)^{3/2}=-\sqrt{1-x^2}+\ln x^{-1}(1+\sqrt{1-x^2})\qquad(0<x\leq 1)$$

$$\tfrac{2}{3}\xi^{3/2}=\sqrt{x^2-1}-\arccos x^{-1}\qquad(1\leq x<\infty).$$

Thus

**10.4.118** $$v(\xi)=\left(\frac{x^2-1}{x^2\xi}\right)^{1/4}y(x)$$

---

*See page II.

satisfies the equation

**10.4.119**
$$\frac{d^2v}{d\xi^2}+\left[\lambda^2\xi-\frac{5}{16\xi^2}+\frac{\xi^2}{4}\frac{x^2(x^2+4)}{(x^2-1)^3}\right]v=0$$

which is of the form **10.4.111** with $x$ replaced by $\xi$ and $q(\xi, \lambda)$ independent of $\lambda$.

Suppose $\mathscr{R}\lambda\geq 0$, $\mathscr{I}\lambda\neq 0$. By the first equation of **10.4.114** there is a solution $v_0(\xi)$ of **10.4.119,** i.e., a solution $y_0(x)$ of **10.4.117** for which the representation

**10.4.120**
$$v_0(\xi)=\left(\frac{x^2-1}{x^2\xi}\right)^{1/4}y_0(x)=\mathrm{Ai}(-\lambda^{2/3}\xi)[1+O(\lambda^{-1})]$$

holds uniformly in $x$ on $0<x<\infty$ as $|\lambda|\to\infty$.

To identify $y_0(x)$ in terms of $x^{\frac{1}{2}}J_\lambda(\lambda x)$, $x^{\frac{1}{2}}Y_\lambda(\lambda x)$, restrict $x$ to $0<x\leq b<1$ so that by **10.4.118** $\xi$ is negative, and replace the Airy function by its asymptotic representation **10.4.59.** This yields

**10.4.121**
$$\begin{aligned}y_0(x)&=\left(\frac{x^2-1}{x^2\xi}\right)^{-1/4}\frac{1}{2}\pi^{-1/2}\lambda^{-1/6}(-\xi)^{1/4}\exp\left(\frac{2}{3}\lambda(-\xi)^{3/2}\right)[1+O(\lambda^{-1})]\\&=\frac{1}{2}\pi^{-1/2}\lambda^{-1/6}\left(\frac{1-x^2}{x^2}\right)^{-1/4}\exp\left(\frac{2}{3}\lambda(-\xi)^{3/2}\right)[1+O(\lambda^{-1})]\end{aligned}$$

Let now $\lambda$ be fixed and $x\to 0$ in **10.4.121.** There results

**10.4.122** $$y_0(x)\sim\tfrac{1}{2}\pi^{-1/2}\lambda^{-1/6}x^{1/2}\left(\tfrac{1}{2}x\right)^\lambda e^\lambda.$$

On the other hand, $y_0(x)$ is a solution of **10.4.117** and therefore it can be written in the form

**10.4.123** $$y_0(x)=x^{1/2}[c_1J_\lambda(\lambda x)+c_2Y_\lambda(\lambda x)]$$

where, from **9.1.7** for $\lambda$ fixed and $x\to 0$

$$J_\lambda(\lambda x)\sim\frac{(\frac{1}{2}\lambda x)^\lambda}{\Gamma(\lambda+1)},$$

$$Y_\lambda(\lambda x)\sim\frac{(\frac{1}{2}\lambda x)^\lambda}{\Gamma(\lambda+1)}\cot\lambda\pi-\frac{(\frac{1}{2}\lambda x)^{-\lambda}}{\Gamma(1-\lambda)}\csc\lambda\pi.$$

Thus, letting $x\to 0$ in **10.4.123** and comparing the resulting relation with **10.4.122** one finds that $c_2=0$ and

**10.4.124** $$y_0(x)=\tfrac{1}{2}\pi^{-1/2}\lambda^{-\lambda-1/6}e^\lambda\Gamma(\lambda+1)x^{1/2}J_\lambda(\lambda x).$$

It follows from **10.4.120** that uniformly in $x$ on $0<x<\infty$

**10.4.125**
$$J_\lambda(\lambda x)=\frac{2\pi^{1/2}}{\Gamma(\lambda+1)}\lambda^{\lambda+1/6}e^{-\lambda}\left(\frac{x^2-1}{\xi}\right)^{-1/4}\mathrm{Ai}(-\lambda^{2/3}\xi)[1+O(\lambda^{-1})]\qquad(|\lambda|\to\infty)$$

## 10.5. Use and Extension of the Tables

### Spherical Bessel Functions

To compute $j_n(x)$, $y_n(x)$, $n=0, 1, 2$, for values of $x$ outside the range of **Table 10.1,** use formulas **10.1.11, 10.1.12** and obtain values for the circular functions from **Tables 4.6–4.8.**

**Example 1.** Compute $j_1(x)$ for $x=11.425$.

From **10.1.11,** $j_1(x)=\frac{\sin x}{x^2}-\frac{\cos x}{x}\cdot$ Hence, using **Tables 4.6** and **4.8,**

$$\begin{aligned}j_1(11.425)&=-\frac{.90920\ 500}{(11.425)^2}-\frac{.41634\ 873}{11.425}\\&=-.00696\ 54535-.03644\ 1902\\&=-.04340\ 7356.\end{aligned}$$

To compute $j_n(x)$, $11\leq n\leq 20$, for a value of $x$ within the range of **Table 10.3,** obtain from **Table 10.3,** directly or possibly by linear interpolation, $j_{21}(x)$, $j_{20}(x)$ and use these as starting values in the recurrence relation **10.1.19** for decreasing $n$.

An alternative procedure which often yields better accuracy and which also applies to computations of $j_n(x)$ when both $n$ and $x$ are outside the range of **Table 10.1** is the following device essentially due to J. C. P. Miller [9.20].

At some value $N$ larger than the desired value $n$, assume tentatively $F_{N+1}=0$, $F_N=1$ and use recurrence relation **10.1.19** for decreasing $N$ to obtain the sequence $F_{N-1}, \ldots, F_0$. If $N$ was chosen large enough, each term of this sequence up to $F_n$ is proportional, to a certain number of significant figures, to the corresponding term in the sequence $j_{N-1}(x), \ldots, j_0(x)$ of true values. The factor of proportionality, $p$, may be obtained by comparing, say, $F_0$ with the true value $j_0(x)$ computed separately. The terms in the sequence $pF_0, \ldots pF_n$ are then accurate to the number of significant figures present in the tentative values. If the accuracy obtained is not sufficient, the process may be repeated by starting from a larger value $N$.

**Example 2.** Compute $j_{15}(x)$ for $x=24.6$.

Interpolation in **Table 10.3** yields for $x=24.6$

$$x^{-21}e^{x^2/86}j_{21}(x)=(-28)3.934616$$
$$x^{-20}e^{x^2/82}j_{20}(x)=(-27)9.48683$$

whence

$$j_{21}(24.6)=.05604\ 29,\ j_{20}(24.6)=.03896\ 98.$$

From the recurrence relation **10.1.19** there results

$j_{19}(24.6)=\phantom{-}.00890\ 67660$ [.00890 70]
$j_{18}(24.6)=-.02484\ 93173$ [−.02485 90]
$j_{17}(24.6)=-.04628\ 17554$ [−.04628 16]
$j_{16}(24.6)=-.04099\ 87086$ [−.04099 88]
$j_{15}(24.6)=-.00871\ 65122$ [−.00871 67]

For comparison, the correct values are shown in brackets.

To compute $j_{15}(x)$ for $x=24.6$ by Miller's device, take, for example, $N=39$ and assume $F_{40}=0$, $F_{39}=1$. Using **10.1.19** with decreasing $N$, i.e., $F_{N-1}=[(2N+1)/x]F_N-F_{N+1}$, $N=39, 38, \ldots, 1, 0$, generate the sequence $F_{38}, F_{37}, \ldots, F_1, F_0$, compute from **Table 4.6**, $j_0(24.6)=(\sin 24.6)/24.6=-.02064\ 620296$, and obtain the factor of proportionality

$$p=j_0(24.6)/F_0=.00000\ 03839\ 17642.$$

The value $pF_{15}$ equals $j_{15}(24.6)$ to 8 decimals. The final part of the computations is shown in the following table, in which the correct values are given for comparison.

It may be observed that the normalization of the sequence $F_N, F_{N-1}, \ldots, F_0$ can also be obtained from formula **10.1.50** by computing the sum $\sigma=\sum_0^\infty (2k+1)F_k^2$ and finding $p=1/\sqrt{\sigma}$. This yields, in the case of the example, $p=1/\sqrt{\sigma}=.00000\ 03839\ 177$.

### Modified Spherical Bessel Functions

To compute $\sqrt{\frac{1}{2}\pi/x}I_{n+\frac{1}{2}}(x)$, $\sqrt{\frac{1}{2}\pi/x}K_{n+\frac{1}{2}}(x)$, $n=0, 1, 2, \ldots$ for values of $x$ outside the range of **Table 10.8,** use formulas **10.2.13, 10.2.14** together with **10.2.4** and obtain values for the hyperbolic and exponential functions from **Tables 4.4** and **4.15.** In those cases when $\sqrt{\frac{1}{2}\pi/x}I_{n+\frac{1}{2}}(x)$ and $\sqrt{\frac{1}{2}\pi/x}I_{-n-\frac{1}{2}}(x)$ are nearly equal, i.e., when $x$ is sufficiently large, compute $\sqrt{\frac{1}{2}\pi/x}K_{n+\frac{1}{2}}(x)$ from formula **10.2.15,** for which the coefficients $(n+\frac{1}{2}, k)$ are given in **10.1.9.**

**Example 3.** Compute $\sqrt{\frac{1}{2}\pi/x}I_{5/2}(x)$, $\sqrt{\frac{1}{2}\pi/x}K_{5/2}(x)$ for $x=16.2$.

From **10.2.13,** $\sqrt{\frac{1}{2}\pi/x}I_{5/2}(x)=(3+x^2)\sinh x/x^3-3\cosh x/x^2$; from **Table 4.4,** $\cosh 16.2=(6)5.4267\ 59950$ and this equals the value of $\sinh 16.2$ to the same number of significant figures. Hence

$$\begin{aligned}\sqrt{\tfrac{1}{2}\pi/16.2}\,I_{5/2}(16.2)&=(.06243\ 402371\\&\quad-.01143\ 118427)[(6)5.4267\ 59950]\\&=338814.4594-62034.29298\\&=276780.1664.\end{aligned}$$

To compute $\sqrt{\frac{1}{2}\pi/16.2}K_{5/2}(16.2)$ use **10.2.17** and obtain

$$\begin{aligned}\sqrt{\tfrac{1}{2}\pi/16.2}\,K_{5/2}(16.2)&=\pi e^{-16.2}\left[\frac{1}{32.4}+\frac{6}{(32.4)^2}+\frac{12}{(32.4)^3}\right]\\&=(-7)2.8945\ 38069[.036932\ 60400]\\&=(-8)1.0690\ 28283.\end{aligned}$$

To compute $\sqrt{\frac{1}{2}\pi/x}I_{n+\frac{1}{2}}(x)$, $3\leq n\leq 8$, for a value of $x$ within the range of **Table 10.9,** obtain from **Table 10.9,** $\sqrt{\frac{1}{2}\pi/x}I_{19/2}(x)$, $\sqrt{\frac{1}{2}\pi/x}I_{21/2}(x)$ for the desired value of $x$ and use these as starting values in the recurrence relation **10.2.18** for decreasing $n$.

To compute $\sqrt{\frac{1}{2}\pi/x}K_{n+\frac{1}{2}}(x)$ for some integer $n$ outside the range of **Table 10.9,** obtain from **10.2.15** or from **Table 10.8,** $\sqrt{\frac{1}{2}\pi/x}K_{\frac{1}{2}}(x)$, $\sqrt{\frac{1}{2}\pi/x}K_{3/2}(x)$ for the desired value of $x$ and use these as starting values in the recurrence relation **10.2.18** for increasing $n$. If $x$ lies within the range of **Table 10.9** and $n>10$, the recurrence may be started with $\sqrt{\frac{1}{2}\pi/x}K_{19/2}(x)$, $\sqrt{\frac{1}{2}\pi/x}K_{21/2}(x)$ obtained from **Table 10.9.**

**Example 4.** Compute $\sqrt{\frac{1}{2}\pi/x}K_{11/2}(x)$ for $x=3.6$. Obtain from **Table 10.8** for $x=3.6$

$$\sqrt{\tfrac{1}{2}\pi/x}\,K_{1/2}(x)=.01192\ 222$$

$$\sqrt{\tfrac{1}{2}\pi/x}\,K_{3/2}(x)=.01523\ 3952$$

The recurrence relation **10.2.18** yields successively

$$-\sqrt{\tfrac{1}{2}\pi/3.6}\,K_{5/2}(3.6)=-.01192\ 222\\ -\frac{3}{3.6}\,(.01523\ 3952)\\ =-.02461\ 718$$

$$\sqrt{\tfrac{1}{2}\pi/3.6}\,K_{7/2}(3.6)=.01523\ 3952\\ +\frac{5}{3.6}\,(.02461\ 718)\\ =.04942\ 4480$$

$$-\sqrt{\tfrac{1}{2}\pi/3.6}\,K_{9/2}(3.6)=-.02461\ 718\\ -\frac{7}{3.6}\,(.04942\ 4480)\\ =-.12072\ 034$$

$$\sqrt{\tfrac{1}{2}\pi/3.6}\,K_{11/2}(3.6)=.04942\ 4480\\ +\frac{9}{3.6}\,(.12072\ 034)\\ =.35122\ 533.$$

As a check, the recurrence can be carried out until $n=9$ and the value of $\sqrt{\tfrac{1}{2}\pi/3.6}\,K_{19/2}(3.6)$ so obtained can be compared with the corresponding value from **Table 10.9.**

To compute $\sqrt{\tfrac{1}{2}\pi/x}\,I_{n+\frac{1}{2}}(x)$ when both $n$ and $x$ are outside the range of **Table 10.9,** use the device described in [9.20].

### Airy Functions

To compute $\mathrm{Ai}(x)$, $\mathrm{Bi}(x)$ for values of $x$ beyond 1, use auxiliary functions from **Table 10.11.**

**Example 5.** Compute $\mathrm{Ai}(x)$ for $x=4.5$.

First, for $x=4.5$,

$$\xi=\tfrac{2}{3}x^{3/2}=6.36396\ 1029,\ \xi^{-1}=.15713\ 48403.$$

Hence, from **Table 10.11,** $f(-\xi)=.55848\ 24$ and thus

$$\begin{aligned}\mathrm{Ai}\,(4.5)&\\ &=\tfrac{1}{2}(4.5)^{-1/4}(.55848\ 24)\ \exp\,(-6.36396\ 1029)\\ &=\tfrac{1}{2}(.68658\ 905)(.55848\ 24)(.00172\ 25302)\\ &=.00033\ 02503.\end{aligned}$$

To compute the zeros $c$, $c'$ of a solution $y(x)$ of the equation $y''-xy=0$ and of its derivative $y'(x)$, respectively, the following formulas may be used, in which $d$, $d'$ denote approximations to $c$, $c'$ and $u=y(d)/y'(d)$, $v=y'(d')/d'^2y(d')$.

$$c=d-u-2d\,\frac{u^3}{3!}+2\,\frac{u^4}{4!}-24d^2\,\frac{u^5}{5!}\\ +88d\,\frac{u^6}{6!}-(88+720d^3)\,\frac{u^7}{7!}\\ +5856d^2\,\frac{u^8}{8!}-(16640d+40320d^4)\frac{u^9}{9!}+\ldots$$

$$c'=d'\left\{1-v-\frac{v^2}{2!}-(3+2d'^3)\frac{v^3}{3!}-(15+10d'^3)\frac{v^4}{4!}\right.\\ -(105+76d'^3+24d'^6)\frac{v^5}{5!}\\ \left.-(945+756d'^3+272d'^6)\frac{v^6}{6!}-\ldots\right\}$$

$$y'(c)=y'(d)\left\{1-d\,\frac{u^2}{2!}+\frac{u^3}{3!}-3d^2\,\frac{u^4}{4!}+14d\,\frac{u^5}{5!}\right.\\ -(14+45d^3)\frac{u^6}{6!}+471d^2\,\frac{u^7}{7!}\\ \left.-(1432d+1575d^4)\frac{u^8}{8!}+\ldots\right\}$$

$$y(c')=y(d')\left\{1-d'^2\,\frac{v^2}{2!}-d'^3\,\frac{v^3}{3!}-(3d'^3+3d'^6)\frac{v^4}{4!}\right.\\ -(15d'^3+14d'^6)\frac{v^5}{5!}\\ \left.-(105d'^3+101d'^6+45d'^4)\frac{v^6}{6!}-\ldots\right\}$$

**Example 6.** Compute the zero of $y(x)=\mathrm{Ai}(x)-\mathrm{Bi}(x)$ near $d=-.4$.

From **Table 10.11,**

$$y(-.4)=.02420\ 467,\ y'(-.4)=-.71276\ 627$$

whence $u=y(-.4)/y'(-.4)=-.03395\ 8776$. From the above formulas

$$\begin{aligned}c&=-.4+.03395\ 8776-.00000\ 5221\\ &\qquad+.00000\ 0111+.00000\ 0001\\ &=-.36604\ 6333.\\ y'(c)&=(-.71276\ 627)\{1+.00023\ 0640\\ &\qquad-.00000\ 6527-.00000\ 0027+.00000\ 0002\}\\ &=(-.71276\ 627)(1.00022\ 4088)\\ &=-.71292\ 599.\end{aligned}$$
